Perfectionism and PERMA: The Benefits of Other-Oriented Perfectionism
PERFECTIONISM AND PERMA

Abstract

The two-factor theory of perfectionism differentiates between positive and negative forms, yet some researchers still argue that perfectionism, as a whole, is detrimental to wellbeing. To this end, the present study investigated the relationship between the tripartite model of perfectionism and the PERMA model of wellbeing, with specific attention given to the relationship each form of perfectionism had with each element of wellbeing. Ninety-two participants (\(M_{\text{age}}=24.99\)) completed online self-report measures of perfectionism (self-oriented, other-oriented, and socially prescribed) and PERMA (positive emotion, engagement, relationships, meaning and accomplishment). Results showed that perfectionism accounted for a substantial amount of variance in all elements of wellbeing. A series of multiple regressions showed that socially prescribed perfectionism negatively predicted all PERMA elements. Self-oriented perfectionism positively predicted positive emotion, engagement, meaning and accomplishment. Other-oriented perfectionism positively predicted meaning and accomplishment. As for overall wellbeing, socially prescribed perfectionism was a negative predictor whereas self-oriented and other-oriented perfectionism were positive predictors. The findings indicate that self-oriented perfectionism is an adaptive form of perfectionism conducive to flourishing whereas socially prescribed perfectionism is a maladaptive form which undermines it. As for other-oriented perfectionism, the findings indicate it is an adaptive form and challenge the view that this “dark” form of perfectionism cannot enhance wellbeing.

Keywords: perfectionism, other-oriented perfectionism, flourishing, wellbeing, PERMA
1. Introduction

Perfectionism is a multidimensional personality trait characterised by striving for flawlessness, setting extremely high standards of performance, tendencies to be overly critical of one’s own behaviour and concern about negative evaluation by others (Frost, Marten, Lahart & Rosenblate, 1990; Hewitt & Flett, 1991; Stoeber, 2017). This differs from early conceptualisations which portrayed perfectionism as one-dimensional; it being a tendency to hold excessively high standards for oneself (Flett, Hewitt & Dyck, 1989; Pirot, 1986). This negative view was supported by evidence from clinical populations, suggesting perfectionism was concurrent with personality disorders and psychopathologies (Druss & Silverman, 1979; Hewitt & Dyck, 1986; Pirot, 1986). However, such findings are unsurprising, given the measures in use were intended to evaluate perfectionisms maladaptive dimensions (e.g. Burns Perfectionism scale; Burns, 1980; the Eating Disorders Inventory Perfectionism subscale; Garner, Olmstead & Polivy, 1983). With the development of more comprehensive measures (Frost et al., 1990; Hewitt & Flett, 1991, 2004) and evidence from non-clinical populations (e.g. Gaudreau & Verner-Filion, 2012; Kanten & Yesıltas, 2015; Stoeber & Rambow, 2007; Suh, Gnilka & Rice, 2017), there is now evidence in favour of an adaptive form of perfectionism. That said, the debate continues as to whether perfectionism undermines or supports flourishing (Flett & Hewitt, 2015; Stoeber & Corr, 2016); a term used to describe high levels of subjective wellbeing arising from functioning well across multiple psychosocial domains (Butler & Kern, 2016; Hone, Jarden, Schofield, Duncan, 2014).1

1.1. The Dimensions of Perfectionism

The notion of perfectionism having two faces is far from novel, with Hamachek (1978) forty years ago proposing the existence of “normal” and “neurotic” perfectionism. However, 

---

1 The terms flourishing and wellbeing will be used interchangeably from hereon in.
PERFECTIONISM AND PERMA

it was not until the 1990s that two groups of researchers introduced the contemporary theory of multidimensional perfectionism; recognising that the construct can comprise both intrapersonal and interpersonal elements (Frost et al., 1990; Hewitt & Flett, 1991). Frost et al. (1990) identified six perfectionism dimensions: excessive concern over making mistakes, high personal standards, perception of high parental expectations, perception of high parental criticism, doubting the quality of one’s actions and preference for order and organisation. More concisely, Hewitt and Flett (1991) identified just three forms: self-oriented (SOP), other-oriented (OOP) and socially prescribed perfectionism (SPP). Best distinguished by whom the perfectionistic behaviour is directed at/attributed to, SOP is characterised by perfectionistic behaviour directed towards the self, such as setting high standards for oneself (Hewitt & Flett, 1991, 2004). Other-oriented perfectionism involves the expectations an individual has about the abilities of others, such as setting unrealistic standards for people around them and placing importance on others being perfect (Hewitt & Flett, 1991). Lastly, SPP describes the need to meet expectations imposed by others; the belief that others have high expectations of them and will only be satisfied when perfectionism is obtained (Hewitt & Flett, 1991, 2004).

1.2. Adaptive and Maladaptive Perfectionism

Although the differences between Frost et al. (1990) and Hewitt and Flett’s (1991, 2004) models of perfectionism are apparent, there is evidence they share the same underlying dimensions, with several authors having derived two-factor solutions (Bieling, Israeli & Antony, 2004; Cox, Enns & Clara, 2002; Dunkley, Zuroff & Blankstein, 2003; Frost, Heimberg, Holt, Mattia & Neubauer, 1993; Stoeber & Otto, 2006). According to this two-factor theory, perfectionism can be split into two superordinate dimensions. Concern over mistakes, parental expectations and concerns, doubts over actions and SPP load on to a maladaptive form of perfectionism coined “perfectionistic concerns”, whereas personal
PERFECTIONISM AND PERMA

standards, organisation, SOP and OOP load on to an adaptive form of perfectionism referred to as “perfectionistic strivings” (Stoeber & Otto, 2006). Furthermore, Stoeber and Otto’s (2006) seminal review concluded perfectionistic concerns were consistently associated with higher levels of negative affect and depression. Moreover, perfectionistic strivings were associated with higher levels of extraversion and conscientIOUSness (traits associated with positive affect and meaning in life; Lightsey et al., 2014; Lucas, Le & Dyrenforth, 2008), higher levels of subjective wellbeing and lower levels of attachment avoidance, anxiety and suicidal ideation (Stoeber & Otto, 2006). As such, the opposing relationships these two superordinate dimensions have with positive and negative characteristics suggests that perfectionistic concerns would contraindicate flourishing, whereas perfectionistic strivings would enhance it.

1.3. Perfectionism and Wellbeing

Indeed, the past decade has seen numerous studies reporting perfectionistic strivings to be associated with a multitude of positive attributes such as higher levels of engagement, meaning in life, positive affect, vitality and life satisfaction (Gaudreau & Verner-Filion, 2012; Kanten & Yesiltas, 2015; Stoeber & Rambow, 2007) which theoretically would enhance subjective wellbeing. However, the traditional view that perfectionism in general is wholly detrimental perseveres. Flett and Hewitt (2015), two of the forefathers of contemporary perfectionism theory, still advocate for the management of perfectionism to promote flourishing, stating that “the cost of perfectionism often outweighs the benefits such that perfectionism is far from synonymous with mental health and wellbeing” (p. 46). Their staunch position presents a challenge for evidence and theory that suggests perfectionism is not always associated with deleterious outcomes (Gaudreau & Verner-Filion, 2012; Kanten & Yesiltas, 2015; Stoeber & Otto, 2006; Stoeber & Rambow, 2007). However, at the time of Flett and Hewitt’s (2015) publication, no empirical studies had directly investigated the
relationship between perfectionism and flourishing. As such, whilst there was evidence to support perfectionistic strivings being associated with positive characteristics (e.g. Gaudreau & Verner-Filion, 2012; Stoeber & Otto, 2006; Stoeber & Rambow, 2007) which one could postulate would support flourishing, there was no verifiable published evidence with which to solidly dispute Flett and Hewitt’s (2015) claims.

To this end, Stoeber and Corr (2016) published the first empirical paper on perfectionism and flourishing, investigating in a student sample whether perfectionistic concerns and perfectionistic strivings (Stoeber & Otto, 2006) showed different relationships with flourishing. Using SPP and SOP as indicators of perfectionistic concerns and perfectionistic strivings respectively, perfectionism explained a medium-large percentage of the variance in flourishing (17.8%); suggesting it is an important personality trait to consider when accounting for individual differences in wellbeing. Moreover, SPP showed a negative relationship with flourishing and SOP a positive one, providing further evidence for the two-factor theory. Interestingly however, OOP did not significantly contribute to their regression model. Although OOP is under researched in comparison to its counterparts (Stoeber, 2014, 2015), a possible explanation for this may lie in OOP’s positive relationship with the Dark Triad (Smith et al., 2017; Stoeber, 2014; Stoeber, Sherry & Nealis, 2015), a term used to describe narcissism, Machiavellianism and subclinical psychopathy; three socially aversive, yet non-pathological personality constructs (Paulhus & Williams, 2002). Furthermore, OOP has been reported to have positive associations with reduced interest in prosocial and intimacy goals, uncaring traits and an individualistic orientation (Stoeber, 2014, 2015). As a result, OOP has been coined a “dark” form of perfectionism, with Stoeber (2014) suggesting it should no longer be considered an indicator of perfectionistic strivings, leading several papers to now exclude it from their definitions of adaptive perfectionism (Stoeber & Damian, 2016; Stoeber & Gaudreau, 2017).
PERFECTIONISM AND PERMA

1.4. The Difficulty of Defining Wellbeing

Nevertheless, whilst Stoeber and Corr’s (2016) findings are salient and provide a starting point for investigation, the study had its limitations. First, the use of the Flourishing Scale (Diener et al., 2010) is problematic. Although reported as having good internal consistency (Cronbach’s alpha .87 to .91; Diener et al., 2010; Hone, Jarden & Schofield, 2014), the issue remains that flourishing has different theoretical and conceptual definitions (Hone, Jarden, Schofield & Duncan, 2014). As such, each conceptual model may show different relationships with the three forms of perfectionism. Furthermore, it is unclear if these multiple models capture distinct or similar types of wellbeing (Goodman, Disabato, Kashdan & Kaufmann, 2017). For example, some models focus on hedonic wellbeing (e.g. Bradburn, 1969); defined in terms of pleasure seeking and pain avoidance, others eudaimonic wellbeing (e.g. Ryff 1989); which focuses on meaning and being fully-engaged in life, and others use a blend of the two (Butler & Kern, 2016; Disabato, Goodman, Kashdan, Short & Jarden, 2016; Huppert & So, 2013; Ryan & Deci, 2001).

To illustrate, Ryff’s (1989) model of psychological wellbeing has six dimensions (autonomy, environmental mastery, personal growth, positive relations with others, purpose in life and self-acceptance) whereas Diener et al.’s (2010) conceptualisation focusses on psychosocial prosperity and has eight dimensions (purpose/meaning, positive relationships, engagement, social contribution, competence, self-respect, optimism and social relationships). In contrast, Seligman’s (2011) PERMA model proposes that wellbeing is comprised of five measurable elements (positive emotion, engagement, relationships, meaning and accomplishment). Conversely, Huppert and So (2013) define flourishing as a combination of feeling good and functioning effectively with 10 components (positive relationships, engagement, meaning, self-esteem, positive emotion, competence, optimism, emotional stability, vitality and resilience), and Rusk and Waters (2015) have recently introduced a five-
PERFECTIONISM AND PERMA

factor model (attention and awareness, comprehension and coping, emotions, goals and habits, and virtues and relationships).

Clearly these models share similar components, however some elements are unique to specific models such as autonomy and optimism (Diener et al., 2010; Ryff, 1989). This is a problem for researchers as use of one conceptual model may neglect the contribution of a component that another model claims is a key element of wellbeing. As such, inclusion or exclusion of a component could alter the outcome of findings and lead to equivocal results. It therefore remains a matter for empirical investigation to determine if Stoeber and Corr’s (2016) findings remain congruent when using different conceptual models of flourishing. This considered, the problem with Stoeber and Corr’s (2016) use of the eight-item Flourishing scale (Diener et al., 2010) becomes clear. With only one item to measure each component of flourishing, the scales brevity does not allow a comprehensive assessment of each element of flourishing and as such is only suitable for use as a brief indicator of flourishing.

1.5. The PERMA Model

Of the conceptualisations discussed, the PERMA model (Seligman, 2011) most closely follows the law of parsimony, providing a definition of flourishing that encompasses elements of other models and has a mix of hedonic and eudaimonic elements. For example, positive emotion is a hedonic element encompassing pleasure, ecstasy, comfort and warmth (Seligman, 2011), also found in Huppert and So (2013) and Rusk and Waters (2015) models. Engagement focuses largely on flow; complete absorption in an activity where individuals are fully involved in the moment (Nakamura & Csikszentmihalyi, 2014; Seligman, 2011), also found in Diener et al. (2010) and Huppert and So’s (2013) models. Relationships is an element found in many models (e.g. Diener et al., 2010; Huppert & So, 2013; Rusk & Waters,
PERFECTIONISM AND PERMA
2015; Ryff, 1989) and refers to positive relationships with other people and the belief that the absence of them is detrimental wellbeing (Seligman, 2011). Meaning is a eudaimonic element best explained as belonging to and serving something bigger than oneself (Seligman, 2011), also found in Diener et al. (2010), Huppert and So (2013) and Ryff’s (1989) models. Finally, accomplishment is also found in multiple models (e.g. Diener et al., 2010; Huppert & So, 2013; Rusk & Waters, 2015; Ryff, 1989) and refers to people pursuing success and working towards goals for their own sake (Butler & Kern, 2016; Seligman, 2011).
Furthermore, the PERMA model (Seligman, 2011), has a validated corresponding measure; the PERMA-Profilser (Butler & Kern, 2016), which is a 23-item measure with three items per PERMA element and eight filler items for health, negative emotion, loneliness and overall happiness. Despite its youth, it has demonstrated internal and cross-time consistency, convergent and divergent validity, and internal consistency of .70 to .88 across the subscales (Butler & Kern, 2016; Iasiello, Bartholomaeus, Jarden & Kelly, 2017) indicating it is a reliable measure (Field, 2013). Moreover, Goodman et al. (2017) found a latent correlation of .98 between the PERMA-Profilser (Butler & Kern, 2016) and subjective wellbeing, suggesting that the PERMA elements are an exceptional indicator of subjective wellbeing and that the PERMA model (Seligman, 2011) is not a distinct type of wellbeing, rather a synonymous measure of it.

1.6. The Present Study

To this end and given the dearth of studies examining perfectionism and flourishing, this provided a clear rationale for the present study to examine the relationship between perfectionism and flourishing using the PERMA model (Seligman, 2011). As the goal was to test the relationships between variables, a cross-sectional correlational design using enter method multiple regressions was deemed most appropriate. Specifically, the aim was to investigate whether SOP, OOP and SPP have different relationships with each PERMA
PERFECTIONISM AND PERMA

element. Despite its age, the tripartite model and its corresponding measure (the Multidimensional Perfectionism Scale [MPS]; Hewitt & Flett, 2004) remains one of the most widely used tools in perfectionism research (e.g. Cox & Hill, 2018; Flett, Nepon, Hewitt & Fitzgerald, 2016; Stoeb, Madigan, Damian, Esposito & Lombardo, 2017). With excellent psychometric properties: evidence of test-retest reliability, convergent and discriminant validity and internal consistency ranging from .74 to .90 across the three forms of perfectionism (see Hewitt & Flett, 2004), use of the MPS for the present study was well justified.

Although the present study was the first to examine the relationship between perfectionism and flourishing using the PERMA model (Seligman, 2011) and as such was exploratory in nature, a number of hypotheses could be formed based on previous studies examining the relationship between perfectionism and positive and negative characteristics. In keeping with Stoeb and Corr's findings (2016) and evidence suggesting SOP is an adaptive form of perfectionism and an indicator of perfectionistic strivings (Bieling et al., 2004; Frost et al., 1993; Stoeb & Otto, 2006), SOP was expected to show a positive relationship with all PERMA elements. Conversely, as evidence suggests SPP is a maladaptive form of perfectionism and an indicator of perfectionistic concerns (Bieling et al., 2004; Frost et al., 1993; Stoeb & Corr, 2016; Stoeb & Otto, 2006), SPP was expected to show a negative relationship with all PERMA elements. As for OOP, given this form of perfectionism is less well researched (Stoeb, 2014, 2015) expectations were less defined. However, as OOP is associated with reduced interest in prosocial and intimacy goals (Stoeb, 2014), OOP was expected to have a negative affinity with the “relationships” element. As for the other PERMA elements, in line with the findings of Stoeb and Corr (2016) and reports that OOP should no longer be considered an indicator of perfectionistic strivings (Stoeb,
PERFECTIONISM AND PERMA

2014), OOP was expected to have no significant relationships with the remaining PERMA elements.

2. Method

2.1. Design

A cross-sectional correlational design was used. The predictor variables were the three forms of perfectionism: SOP, OOP and SPP as assessed by the MPS (Hewitt & Flett, 2004). The outcome variables were the five PERMA elements: positive emotion, engagement, relationships, meaning, accomplishment and overall well-being as measured by the PERMA-Profiler (Butler & Kern, 2016).^2

2.2. Participants

Participants were required to be ≥ 18 years old (no upper age limit and no other exclusion criteria). First and second year undergraduate psychology students were recruited through xxx University’s participation pool; one SONA point granted in return for taking part. No other incentives financial or otherwise were offered or given. Final year undergraduate psychology students and members of the public were recruited via an email with a link to the survey inviting participation.

Of 102 survey responses, 10 were incomplete thus excluded from analysis. Of complete responses (N= 92, 12 males, 79 females, one gender fluid), ages ranged from 18 to 67 (M age= 24.99 years, SD= 11.10). Thirty-four participants reported being single, 43 in a romantic relationship (31 not cohabiting, 13 cohabiting), 11 were married, two were widowed, one was in polyamorous relationships. Regarding ethnicity; 81 participants identified as

---

^2 Health, negative emotion, loneliness and happiness items were included as per Butler and Kern’s (2016) recommendations, however as the focus of the present study was the PERMA elements, these subscales were not included as outcome variables in the subsequent regression analyses.
PERFECTIONISM AND PERMA

white British and six identified as another white background. Two identified as Chinese and
a further two selected multiple categories. One participant could not be categorised. As for
work status; 10 reported working full-time, six working part-time, 57 were full-time students,
one was a part-time student and two were retired. A further 16 fell into two categories; 13
were full-time students working part-time, one was a full-time student retired from
employment, one was working full-time alongside a “bank job”, and one was working full-
time and a full-time student.

2.3. Materials

The three-part survey was created through the Qualtrics online survey platform.
Forced responses were enabled for all questions bar demographics for scoring purposes. First,
participants were asked to provide age, gender, relationship and occupational status and
ethnic background. Ethnic background questions were derived from the Office for National
Statistics recommended harmonised ethnic group questions for use on surveys in England
(Office for National Statistics, 2017). Questions were multiple choice with open-ended
questions included to allow elaboration: e.g. “what do you identify your gender as?”, options
being: “male”, “female”, “prefer not to say” and “other; please state in the box provided”.

2.3.1. Perfectionism. Second, The MPS (Hewitt & Flett, 2004) was used to measure
perfectionism. This 45-item scale has 15 questions for each form of perfectionism; SOP,
OOP and SPP, e.g. “I seldom feel the need to be perfect”; “others will like me even if I don’t
excel at everything”. Items were rated on a scale from 1 to 7 with the end points labelled
(disagree to agree). Items were presented on a Likert like scale and participants asked to
read each item and decide whether they agreed/disagreed, and to what extent. Selecting 1
indicated strong disagreement, 7 indicated strong agreement, and feeling neutral/undecided
was indicated by selecting 4. High SOP scores evidenced perfectionistic behaviour that
PERFECTIONISM AND PERMA
relates/is directed towards the self (Hewitt & Flett, 2004). Similarly, high OOP scores
evidenced perfectionistic behaviour that relates/is directed towards others and high SPP
scores indicated a perception that other people have perfectionistic standards/expectations for
their behaviour (Hewitt & Flett, 2004). Hewitt and Flett (2004) have reported internal
consistency estimates (Cronbach’s alpha) ranging from .84 to .90 for SOP, 7.4 to .83 for OOP
and .80 to .87 for SPP; demonstrating acceptable to excellent reliability (Field, 2013) with
comparable values from clinical and community samples.

2.3.2. Flourishing. Third, the PERMA-Profiler (Butler & Kern, 2016) was used to
measure flourishing. This 23-item measure has three items per PERMA element and a
further eight filler items; three each for negative emotion and health, and singular items for
happiness and loneliness, e.g. “how often do you become absorbed in what you are doing?”;
“in general, how often do you feel positive?” Overall wellbeing is calculated as the mean of
the PERMA elements and happiness item. Items were rated on a scale from 0 to 10 with the
end points labelled (e.g. never to always; not at all to completely). Items were presented on a
Likert like scale and participants asked to read each question and select the point on the scale
that they felt best described them. Low scores indicated feeling low levels of an element; the
higher the score the more of the element the participant felt they possessed. The PERMA-
Profiler has been reported to have acceptable to excellent reliability, with internal consistency
(Cronbach’s alpha) levels of .88 for positive emotion, .72 for engagement, .82 for
relationships, .90 for meaning, .79 for accomplishment, .71 for negative emotion, .92 for
health and .94 for overall wellbeing (Butler & Kern, 2016; Field, 2013).

2.4. Procedure

The study received ethical approval from xxx University’s Ethics Committee. An
information sheet provided participants with a brief background regarding perfectionism and
stated the study’s purpose. The information sheet assured participants that all answers would
PERFECTIONISM AND PERMA

be anonymous, confidential, stored securely, provided details on how to withdraw, rewards for taking part (i.e. SONA points) and the researchers contact details should further information be required. It was highlighted slight discomfort may be experienced when answering questions relating to wellbeing and if readers felt that this may be applicable not to participate as all questions had to be answered for scoring purposes.

Participants were required to tick a consent box before proceeding to confirm: (i) they understood the nature of the study, (ii) that they were free to withdraw at any time without reason or prejudice and (iii) that the data provided would remain confidential. After giving informed consent, participants entered a unique code word which would identify their data and allow deletion should they wish to withdraw. On completion, participants were thanked and shown a debrief sheet providing a more detailed explanation of the purpose of the project. Contact details were restated, and a reminder given that participants could withdraw any time within a month of completion by contacting the researcher. The total procedure took approximately 10 minutes.
3. Results

3.1. Treatment of Data

All descriptive and inferential statistics were calculated using SPSS Version 24. As seen in Table 1, descriptive statistics and Cronbach’s alpha was calculated for all subscales as a measure of internal consistency. All alpha levels were > .70 indicating good reliability (Field, 2013), except for engagement (α=.53, corrected item-total correlations > .30). That said, scores with alphas < .70 remain useful for research purposes (Nunnally & Bernstein, 1994), therefore engagement was retained for further analyses.

Table 1.

Descriptive statistics and internal consistency for MPS (Hewitt & Flett, 2004) and PERMA-Profiler (Butler & Kern, 2016) subscales (N=92).

3 Cronbach’s alpha could not be calculated for the loneliness and happiness subscales as they are single item measures.
3.2. Analytic Strategy

To assess the relationship between the three forms of perfectionism and the PERMA elements, including overall wellbeing, two analytic strategies were implemented. First, bivariate correlations were computed between all variables. Second, six enter method multiple regressions were conducted to predict each PERMA element and overall wellbeing using the three forms of perfectionism as predictors.

Data from Hewitt and Flett’s (2004) community sample showed men scored significantly higher than women only for the OOP subscale, however the effect was small; accounting for only .7% of the variance. Similarly, age has been reported to affect only SPP (Hewitt & Flett, 2004), with scores decreasing as age increased, however again this effect was small. As such, given only 13% of the participants identified as male and the majority of participants (75%) fell between the ages of 18-24, neither gender nor age was controlled for in the subsequent analyses.

3.3. Bivariate Correlations

Bivariate Pearson’s correlations were run between all variables, using an alpha level of .05 (see Table 2). As per Cohen’s (1992) effect size guidelines and in line with previous findings (Hewitt & Flett, 2004), SOP displayed a medium significant positive correlation with OOP and a large significant positive correlation with SPP, however contrary to expectations, OOP was and SPP were not significantly correlated.
PERFECTIONISM AND PERMA

As seen in Table 2, contrary to expectations, SOP was not significantly correlated with any outcome variables. However, given SOP displayed medium/large significant correlations with SPP and OOP, this indicates there was significant overlap between them. In other words, those with higher levels of one form of perfectionism tended to have higher levels of the other forms of perfectionism as well. As such, this may have resulted in some significant relationships being suppressed and others being inflated as has been previously reported by Hill, Huelsman and Araujo (2010) and Stoeber, Harvey, Almeida and Lyons (2013).

Unexpectedly, OOP displayed medium significant positive correlations with meaning and accomplishment and a small-medium significant positive correlation with overall wellbeing. Socially prescribed perfectionism on the other hand showed medium-large significant positive correlations with negative emotion and loneliness. In line with expectations, SPP also displayed large significant negative correlations with positive emotion, relationships and overall wellbeing, medium-large significant negative correlations with happiness and medium significant negative correlations with engagement, meaning, accomplishment and health.

3.4. Multiple Regression Analyses

Next, six enter method multiple regressions were conducted to predict each PERMA element and overall wellbeing from SOP, OOP and SPP (coefficients and 95% confidence intervals for the unstandardised beta values seen in Table 3). To satisfy the assumptions of multiple regression, scatterplots confirmed the relationships between all predictor and outcome variables were linear. As variance inflation factor scores were < 10 (Myers, 1990) and tolerance scores were > 0.2 (Menard, 1995) for all models, the assumption of no multicollinearity was met. The Durbin-Watson statistic showed the values of the residuals were independent as the values for all models were close to 2 (Field, 2013). Scatterplots of the
PERFECTIONISM AND PERMA

standardised residual versus standardised predicted values did not funnel out for any of the
models, suggesting the assumption of homoscedasticity had been met (Field, 2013).

Probability-plots were approximately linear, suggesting that the assumption of normality of
the residuals was met for the positive emotion, engagement, meaning and overall wellbeing
models, but may have been violated for the relationships and accomplishment models.

However, as only extreme deviations are likely to have a significant impact, the results likely
remain valid. Finally, for all models Cook’s Distance values were < 1, suggesting there were
no influential cases biasing any of the models (Field, 2013).

Note. N=92, SE=Standard Error, *p<.05, **p<.01, ***p<.001.

3.4.1. Positive emotion. The model, with the three predictors reached significance and was able to account for 32.7% of the variance in positive emotion, (R²= .327, F(3,88)= 14.27, p< .001). As seen in Table 3, SPP (β= -.63; t(88)= -6.39, p< .001) and SOP (β= .26; t(88)= 2.50, p= .014) both made significant contributions to the regression, meaning positive emotion was predicted by SOP and SPP. Other-oriented perfectionism (β= .11; t(88)= 1.21, p= .230) however did not make a significant contribution.

3.4.2. Engagement. The model reached significance, accounting for 17.1% of the variance in engagement, (R²=.171, F(3,88)= 6.04, p= .001). Socially prescribed perfectionism (β= -.43; t(88)= -3.89, p< .001) and SOP (β= .33; t(88)= 2.89, p= .005) both made significant contributions to the regression, meaning engagement was predicted by SOP and SPP. Again OOP (β= .06; t(88)= .60, p= .549) did not make a significant contribution to the regression.

3.4.3. Relationships. The model reached significance, accounting for 36% of the variance in relationships, (R²= .360, F(3,88)= 16.52, p< .001). Socially prescribed perfectionism (β= -.65; t(88)= -6.69, p< .001) was the only predictor to make a significant contribution to the regression, meaning positive relationships were negatively predicted by SPP. Neither SOP (β= .15; t(88)= 1.49, p= .14) nor OOP (β= .14; t(88)= 1.60, p= .113) made significant contributions.
PERFECTIONISM AND PERMA

3.4.4. Meaning. The model reached significance, accounting for 22.5% of the variance in meaning, (R² = .225, F(3,88) = 8.52, p < .001). All three forms of perfectionism made significant contributions to the regression; SPP (β = -.45; t(88) = -4.25, p < .001), SOP (β = .25; t(88) = 2.20, p = .030), OOP (β = .23; t(88) = 2.34, p = .022), indicating that meaning was predicted by SPP, SOP and OOP.

3.4.5. Accomplishment. The model reached significance, accounting for 29.3% of the variance in accomplishment, (R² = .293, F(3,88) = 12.14, p < .001). Again, all three forms of perfectionism made significant contributions to the regression; SPP (β = -.50; t(88) = -4.95, p < .001), OOP (β = .29; t(88) = 3.00, p = .004), SOP (β = .27; t(88) = 2.51, p = .014), meaning that accomplishment was predicted by SPP, OOP and SOP.

3.4.6. Overall wellbeing. The model reached significance, accounting for 34.3% of the variance in overall wellbeing (R² = .343, F(3,88) = 15.31, p < .001). Again, all three forms of perfectionism made significant contributions to the regression; SPP (β = -.62; t(88) = -6.34, p < .001), SOP (β = .29; t(88) = 2.79, p = .006), OOP (β = .19; t(88) = 2.10, p = .039), indicating that overall wellbeing was predicted by SPP, SOP and OOP.

In summary, the results showed that perfectionism explained a substantial amount of variance in all PERMA elements and overall wellbeing. All models reached significance at the .05 alpha level. Socially prescribed perfectionism was a significant negative contributor to all models. In contrast, SOP significantly positively contributed to all models bar the relationships model and OOP significantly positively contributed to the meaning, accomplishment and overall wellbeing models.

4. Discussion

4.1. The Present Findings

The aim of the present study was to investigate the relationship between the tripartite model of perfectionism (Hewitt & Flett, 1991, 2004) and the PERMA model of flourishing (Seligman, 2011); specifically, whether the three forms of perfectionism showed different relationships with each PERMA element. Self-oriented perfectionism was expected to show a positive relationship with all PERMA elements, SPP a negative relationship with all PERMA elements and OOP to show a negative affinity with the “relationships” element but otherwise have no significant relationships with the remaining PERMA elements.

As expected, results showed perfectionism accounted for a large portion of variance in all PERMA elements; confirming perfectionism is a salient personality trait to consider when explaining individual differences in wellbeing. Supporting the hypotheses, those with higher levels of SPP reported lower levels of all PERMA elements. Additionally, SPP was the only predictor to significantly contribute to all models suggesting it has the strongest influence on flourishing of the forms of perfectionism measured. Expectations were partially met for SOP, with it being a positive predictor of positive emotion, engagement, meaning, accomplishment and overall wellbeing, although contrary to expectations it was not a significant predictor of positive relationships. Self-oriented perfectionism was also the second largest contributor to all models (bar relationships), suggesting it influences flourishing, albeit to a lesser extent than SPP. However, contrary to expectations, participants with higher levels of OOP reported higher levels of meaning, accomplishment and overall wellbeing. Other-oriented perfectionism was the smallest contributor to these models, indicating that out of the three forms of perfectionism it has the least (although still significant) influence on flourishing.
PERFECTIONISM AND PERMA

4.2. Confirming Two-Factor Theory

With regards to SOP and SPP, the present results replicate Stoeber and Corr’s (2016) findings and are consistent with research identifying SPP and SOP as maladaptive and adaptive forms of perfectionism respectively; confirming their place as indicators of perfectionistic concerns and perfectionistic strivings (Bieling et al., 2004; Frost et al., 1993; Stoeber & Otto, 2006). The findings partially confirm Flett and Hewitt’s (2015) assertion that perfectionism can undermine flourishing, however crucially neither Stoeber and Corr (2016) nor the present study claimed that all forms of perfectionism would be/are beneficial. Rather both emphasised that different forms of perfectionism would have different (i.e. positive or negative) relationships with flourishing and the PERMA elements that comprise it. As such, whilst the present findings do support the idea that perfectionism can undermine wellbeing, they show that only SPP impedes flourishing and that SOP enhances it; challenging Flett & Hewitt’s (2015) view that perfectionism in general undermines flourishing. Importantly however, the present findings explain almost double the amount of variance in overall flourishing compared to Stoeber and Corr’s (2016) results. This confirms the present study’s earlier contention that using different conceptual models of flourishing would likely lead to different findings. Moreover, this emphasises the importance of looking at the relationship each individual element of flourishing has with each form of perfectionism.

4.3. Adaptive Perfectionism and PERMA

That said the results with regards to SOP must be interpreted with caution. Although SOP was a positive predictor of four out of five PERMA elements, this is inconsistent with the non-significant correlations between SOP and these PERMA elements. This raises the possibility that SOP may have acted as a suppressor variable (a variable that increased the predictive validity of another variable[s] in the regression, through suppression of irrelevant
PERFECTIONISM AND PERMA

variance in them; Conger, 1974; Tabachnick & Fidell, 2014). Similar findings have been reported by Hill et al. (2010) and Stoeber et al. (2013) who both consequently conducted multiple regressions analyses controlling for overlap between the different forms of perfectionism. However, this approach was not warranted here given the exploratory nature of the work, and on balance such methods are discouraged. Indeed, the most notable critique being that the construct the predictor variable represents can change once the shared variance with other predictor variables is removed (Hill, 2014, 2017; Lynam, Hoyle & Newman, 2006). That said, some perfectionism researchers remain highly vocal about the need for overlap between the forms of perfectionism to be controlled for. Both Stoeber and Otto (2006) and Stoeber and Gaudreau (2017) have reported that perfectionistic strivings (represented by SOP in the current study) have stronger relationships with positive attributes when the overlap with perfectionistic concerns (represented by SPP) is controlled for. As such, not controlling for overlap may not only explain why SOP had no significant positive correlations with the PERMA elements, it could also explain why SOP did not make a significant contribution the relationships model.

Additionally, not statistically controlling for overlap may explain why OOP was not a significant negative predictor of positive relationships. However, perhaps this result should not be entirely surprising as the literature regarding OOP and relationships is equivocal. For example, Haring, Hewitt and Flett (2003) reported that whilst OOP in wives was associated with marital problems, the same association was not found for husbands. Similarly, Hewitt, Flett and Mikail (1995) found spouses’ reports of marital adjustment and OOP was only related in some cases, dependant on the role the spouse had in the relationship. This suggests that OOP’s effect on interpersonal relationships is dependent on numerous factors, and as such, simply measuring OOP on its own may not be enough of a reliable indicator to predict feelings of satisfaction in interpersonal relationships.
PERFECTIONISM AND PERMA

4.4. OOP and PERMA

That discussed, the most notable finding was that OOP was a significant positive predictor of overall wellbeing. This differs from Stoeber and Corr’s (2016) results who found no significant relationship between OOP and flourishing. Furthermore, the findings are the antithesis of Stoeber’s (2014) claim that OOP should be removed as an indicator of perfectionistic strivings; an adaptive form of perfectionism. An explanation for the findings may lie in examining the personality traits associated with OOP. For example, conscientiousness (the ability to control impulses, be goal directed and plan and delay gratification; Roberts, Jackson, Fayard, Edmonds & Meints, 2009) is positively correlated with OOP (Hewitt & Flett, 2004) and has been reported to have a moderating effect on OOP, bringing out its “bright side” through encouraging engagement in greater interpersonal citizenship behaviours (Shoss, Callison & Witt, 2015). Therefore, OOP being adaptive or maladaptive may depend on how it interacts in combination with other personality traits within an individual. To this end, although not measured in the present study, the current sample may have had other personality traits at levels to exert a modifying effect, offering an explanation for the present findings.

4.5. OOP, Narcissism and Wellbeing

Additionally, OOP’s positive relationship with the Dark Triad, particularly narcissism (Smith et al., 2017; Stoeber, 2014; Stoeber et al., 2015) may explicate OOP’s positive relationship with overall wellbeing. For example, narcissism is a construct comprised of grandiosity, entitlement, dominance and superiority (Paulhus & Williams, 2002) which previous studies have reported as being beneficial to subjective wellbeing. Rose (2002) reported that overt narcissists (a grandiose self of self, ignorance to others needs and demanding of attention; Wink, 1991) had higher self-esteem, happiness and life satisfaction
PERFECTIONISM AND PERMA
compared to covert narcissists (characterised by feelings of inferiority, hypersensitivity and dissatisfaction; Wink, 1991). Furthermore, Sedikides, Rudich, Gregg, Kumashiro and Rusbult (2004) found that high scores on the Narcissistic Personality Inventory (NPI; Raskin & Terry, 1988) were inversely related to dispositional depression and sadness and positively related to subjective wellbeing. Additionally, Ackerman et al. (2011) found a three-factor solution for the NPI (Raskin & Terry, 1988); Leadership/Authority, Grandiose Exhibitionism and Entitlement/Exploitativeness. Leadership/Authority was linked to adaptive outcomes, whereas the others factors were linked to maladaptive outcomes. This indicates that narcissism being maladaptive is likely dependent on which are the dominant facets. A further consideration is that narcissism has been reported to be more positively correlated with life satisfaction in emerging adults (≤ 25 years old; Hill & Roberts, 2014). As such, given the mean age of participants in the current study was 25, the present sample may have been more likely to experience positive outcomes from any narcissistic traits than would have been found in an older sample.

Furthermore, this positive association with narcissism (Smith et al., 2017; Stoeber, 2014; Stoeber et al., 2015) may also explain OOP being a significant positive predictor of meaning. Several authors have identified narcissism as playing a part in inner emptiness; a state of low positive affect and feeling a lack of purpose or substance (Zerach, 2016). This can be conceptualised as the opposite of meaning; defined as belonging to and serving something bigger than oneself (Seligman, 2011; Zondag, 2005). However, it is again important to consider the different types of narcissism, as covert narcissists are more likely to report experiencing a sense of meaningless in life and the negative affect of emptiness than overt narcissists (Wink & Donahue, 1997; Zerach, 2016; Zondag, Van Halen & Wojtkowiak, 2009). This is consistent with the idea that overt and covert narcissism are at opposite ends of an adjustment continuum; overt narcissism as adaptive and covert narcissism as
PERFECTIONISM AND PERMA maladaptive (Watson, Hickman & Morris, 1996; Zondag, 2013). As such, although not measured in the present study, the current sample may have had higher levels of overt narcissism which could account for those high in OOP reporting feeling that their lives had more meaning.

4.6. OOP, Machiavellianism and Wellbeing

Additionally, OOP’s positive relationship with the Dark Triad (Smith et al., 2017; Stoeber, 2014; Stoeber et al., 2015) may also account for OOP being a significant positive predictor of accomplishment, as Dark Triad traits have been reported to coincide with success in the workplace. For example, Zettler and Solga (2013) reported that Machiavellianism (a manipulative personality trait; Paulhaus & Williams, 2002) was related to job performance in an inverted U-shaped manner; their being an optimal amount of Machiavellianism for succeeding, but too much Machiavellianism being detrimental. Similarly, Spurk, Keller and Hirschi (2016) found that narcissism was positively related to job salary and Machiavellianism to leadership positions and career satisfaction. This suggests that Dark Triad traits are indicators of career success, with Hirschi and Jaensch (2015) proposing those high in these traits have a more active and confident approach which may account for their success. Indeed, this suggestion fits with other personality correlates of OOP such as self/personal control, self-efficacy and assertiveness (Hewitt & Flett, 2004), all of which have been reported to boost career success (Ames, 2009; Duckwork & Gross, 2014; Lisbona, Palaci, Salanova & Frese, 2018). As such, it seems likely those high in OOP may have other personality traits that lend to them being high achievers; therefore, accounting for them reporting a greater sense of accomplishment. In respect to this, future researchers may wish to consider conducting a series of moderation analyses, with overt and covert narcissism as dichotomous moderators, to predict accomplishment, meaning and wellbeing from OOP. To the best of current knowledge this has not yet been investigated and would explore whether
PERFECTIONISM AND PERMA

the relationships between OOP and these outcome variables does indeed differ depending on narcissism subtype.

4.7. The Pygmalion Effect

However, another possible explanation for OOP predicting accomplishment may be the Pygmalion effect; a type of self-fulfilling prophecy where a person (perceiver) raises their expectations of those around them (targets), which results in the targets performance being boosted (Collins, 2011; Duffy, Field & Shirley, 2011; Eden, 1992). First described in an educational context (Rosenthal & Jacobson, 1968) the effect has also been reported in occupational settings (Duan, Li, Xu & Wu, 2017; Eden, 1992), suggesting it is a universal phenomenon. Furthermore, as Leadership/Authority is thought to be a dimension of narcissism (Ackerman., 2011), it may be that those high in OOP tend to take on authoritative roles in their social circle, akin to a teacher or manager where the Pygmalion effect is typically reported (Duan et al., 2017; Eden, 1992). Consequently, those around the individual high in OOP may improve their performance in line with the expectations of the person high in OOP. Indeed, a similar effect has been reported in a sporting context, with OOP (team-oriented perfectionism) positively predicting team performance; the idea being that putting perfectionistic standards on other team members drives the group to better performance (Hill, Stoeber, Brown & Appleton, 2014). Theoretically, this could elicit feelings of accomplishment in the individual high in OOP, especially if they feel part of a successful group which would enhance any narcissistic need for grandiosity, dominance and superiority (Paulhus & Williams, 2002). Alternatively, if those high in OOP feel they have influenced/improved another’s performance, they may feel responsible for the targets success and consequently feel a sense of accomplishment.

4.8. Limitations
PERFECTIONISM AND PERMA

The present study had its limitations, firstly the sample was predominantly female (86%) and as such, results may not be representative of both genders. Secondly, a large portion of the sample were university students (72%). Although a convenient sampling methodology, to fully understand the relationship between perfectionism and flourishing it will be important for future studies to examine this in a sample from the general population. It is also worth considering the survey layout and the impact of having demographic and MPS (Hewitt & Flett, 2004) questions prior to the PERMA-Profilier (Butler & Kern, 2016). According to the Organisation for Economic Co-operation and Development’s (OECD) guidelines on measuring subjective wellbeing (2013), wellbeing items should come immediately after questions that establish eligibility to participate to reduce question order effects and ensure any contextual effects are consistent across surveys. As such, it is possible that individual differences highlighted by the preceding questionnaires may have influenced participant responses on the PERMA-Profilier (Butler & Kern, 2016). Future studies may wish to place wellbeing items at the start of surveys to manage this effect.

The study also used a correlational cross-sectional study design, therefore whilst perfectionism was predictive of flourishing, this should not be interpreted as causation and cannot address directionality. As such, the next step for future researchers will be to investigate whether perfectionism predicts longitudinal changes in flourishing. A further consideration is that the PERMA model of wellbeing (Seligman, 2011) may not be appropriate for other cultures and backgrounds. Typically, western countries such as the United Kingdom (where the present study was conducted) favour hedonism as a way of pursuing happiness, whereas eastern countries favour eudaimonism (Joshanloo, 2014). Furthermore, the importance of wellbeing indicators such as happiness vary across cultures, with western cultures viewing happiness as paramount and positive and eastern cultures viewing happiness as transient, with uncertainty regarding whether it is good (Oshi & Gilbert,
PERFECTIONISM AND PERMA

2016). As such, the present findings may not be applicable to eastern cultures and it will be important for wellbeing researchers in their respective countries to investigate how applicable the PERMA model (Seligman, 2011) is as a measure of how their citizens flourish. Finally, in respect to SOP possibly having acted as a suppressor variable, future studies will need to replicate the findings before firm conclusions can be drawn regarding the relationship between SOP and wellbeing. Despite the practice of partialling out variance being criticised (Hill, 2014, 2017; Lynam et al., 2006), it would be wise for future researchers to control for any overlap between forms of perfectionism when conducting correlations and multiple regressions. Present findings considered, such practices will likely be necessary to accurately show the relationship between the different forms of perfectionism and any outcome variables.

Lastly, it would be remiss not to comment on the poor Cronbach’s alpha for the engagement subscale, which was considerably lower than the generally accepted cut off (<.70; Field, 2013). This is not the first time this subscale has been found to have poor internal consistency. Indeed, closer inspection of Butler and Kern’s (2016) original paper reveals several samples used to test the internal consistency of the PERMA-Profiler fell below .70 for this domain; the only subscale to do so. Iasiello et al. (2017) have also commented on its low internal consistency, and comparable to the present study’s findings, Goodman et al. (2017) found the engagement subscale to have an alpha level of .58. All considered, this suggests that the subscale may not reliably measure engagement, a point for future researchers to consider before choosing this scale and when interpreting the current results.

Future studies may wish to build on the present findings by investigating the relationship between flourishing and other models of perfectionism such as the 2x2 model (Gaudreau & Thompson, 2010) which rather than focussing on perfectionistic strivings and perfectionistic concerns addresses different within person combinations of each subtype.
Additionally, researchers should consider using different indicators of perfectionistic strivings and perfectionistic concerns (Stoeber & Otto, 2006) such as items from the Perfectionism Inventory (Hill et al., 2004), the Almost Perfect Scale-Revised (Slaney, Rice, Mobley, Trippi & Ashby, 2001) or the Big Three Perfectionism Scale (Smith, Saklofske, Stoeber & Sherry, 2016), to see if the present findings are concordant when using alternative measures.

4.9. Conclusions

To conclude, the present findings make a significant contribution to the extant literature on perfectionism and flourishing, being the first to investigate the relationship between perfectionism and the PERMA model of wellbeing (Seligman, 2011). The findings extend the literature by indicating that all three forms of perfectionism are significant predictors of flourishing, explaining a large amount of variance; with SOP and OOP being conducive to flourishing and SPP undermining it. Furthermore, the present findings highlight the importance of examining the relationships each element of flourishing has with each form of perfectionism. Moreover, the results challenge the view that perfectionism in general undermines flourishing and emphasises the importance of looking at perfectionism as a multidimensional trait. The findings support the notion that OOP represents a form of perfectionistic strivings (Bieling et al., 2004; Frost et al., 1993; Stoeber & Otto, 2006), supportive of meaning, accomplishment and overall wellbeing, and counter Stoeber’s (2014) position that it embodies a “dark” form of perfectionism. As previously stated, OOP is commonly ignored in terms of its clinical relevance (Stoeber, 2015; Stoeber & Otto, 2006). However, the present findings clearly indicate that OOP warrants increased research attention to challenge the view that this “dark” form of perfectionism (Stoeber, 2014, 2015) has no effect on flourishing.
