5 (Dated: March 12, 2009)

A general analytical model applicable to flexural-torsional coupled vibration of thin-walled composite box beams with arbitrary lay-ups under a constant axial force has been presented. This model is based on the classical lamination theory and accounts for all the structural coupling coming from the material anisotropy. Equations of motion are derived from the Hamilton's principle. A displacement-based one-dimensional finite element model is developed to solve the problem. Numerical results are obtained for thin-walled composite box beams to investigate the effects of axial force, fiber orientation and modulus ratio on the natural frequencies, load-frequency interaction curves and corresponding vibration mode shapes.

6 Keywords: Thin-walled composite beam; classical lamination theory; flexural-torsional coupled vibration; axial
7 force

8 I. INTRODUCTION

9 Fiber-reinforced composite materials have been used over the past few decades in a variety of structures. Composites
10 have many desirable characteristics, such as high ratio of stiffness and strength to weight, corrosion resistance and
11 magnetic transparency. Thin-walled structural shapes made up of composite materials, which are usually produced by
12 pultrusion, are being increasingly used in many engineering fields. However, the structural behavior is very complex
13 due to coupling effects as well as warping-torsion and therefore, the accurate prediction of stability limit state and
14 dynamic characteristics is of the fundamental importance in the design of composite structures.

15 The theory of thin-walled members made of isotropic materials was first developed by Vlasov [1] and Gjelsvik [2].
16 Up to the present, investigation into the stability and vibrational behavior of these members has received widespread
17 attention and has been carried out extensively. Closed-form solution for flexural and torsional natural frequencies,
18 critical buckling loads of isotropic thin-walled bars are found in the literature (Timoshenko [3,4] and Trahair [5]). For
19 some practical applications, earlier studies have shown that the effect of axial force on the natural frequencies and

; Electronic address: jhlee@sejong.ac.kr

mode shapes is more pronounced than those of the shear deformation and rotary inertia. Although a large number of studies has been performed on the dynamic characteristics of axially loaded isotropic thin-walled beams, it should be noted that only a few deal with thin-walled composite structures with arbitrary lay-ups. A literature survey on the subject shows that there appears some works reported on the free vibration of axially loaded closed-section thin-walled composite beams. Many numerical techniques have been used to solve the dynamic analysis of these members. One of the most effective approach is to derive the exact stiffness matrices based on the solution of the differential equation of beam. Most of those studies adopted an analytical method that required explicit expressions of exact displacement functions for governing equations. Banerjee [6,7] applied the exact dynamic stiffness matrix to perform the free vibration analysis of axially loaded composite Timoshenko beams. The works of Li et al. [8-11] deserved special attention because they developed the analytical solution to determine the flexure-torsion coupled dynamic responses of axially loaded thin-walled composite beam under concentrated, distributed time-dependent loads and external stochastic excitations. The influences of axial force, Poisson effect, axial deformation, shear deformation and rotary inertia were discussed in their research. Kaya and Ozgumus [12] introduced the differential transform method (DTM) to analyse the free vibration response of an axially loaded, closed-section composite Timoshenko beam which featured material coupling between flapwise bending and torsional vibrations. The effects of the bending-torsion coupling, the axial force and the slenderness ratio on the natural frequencies were inspected. In the research of Banerjee and Li et al. and Kaya and Ozgumus [6-12], it was very effective in saving the computing time due to the closed-form solution which can be easily derived by the help of symbolic computation. However, the analytical operations were often too complex to yield exact displacement functions in the case of solving a system of simultaneous ordinary differential equations with many variables. Additionally, they considered only a cantilever glass-epoxy composite beam with rectangular cross section in the numerical examples. By using finite element method, Bank and Kao [13] analysed free and forced vibration of thin-walled fibre reinforced composite material beams by using the Timoshenko beam theory. Song et al. [14] carried out the vibration and stability of pretwisted spinning thin-walled composite beams featuring bending-bending elastic coupling. Recently, Cortinez, Machado and Piovan [15,16] presented a theoretical model for the dynamic analysis of thin-walled composite beams with initial stresses. Machado et al. [17] determined the regions of dynamic instability of simply supported thin-walled composite beam subjected to an axial excitation. The analysis was based on a small strain and moderate rotation theory, which was formulated through the adoption of a second-order displacement field. In their research [15-17], thin-walled composite beams for both open and closed cross-sections and the shear flexibility (bending, non-uniform warping) were incorporated. However, it was strictly valid

49 for symmetric balanced laminates and especially orthotropic laminates. By using using a boundary element method,
 50 Sapountzakis and Tsiatas [18] solved the general flexural-torsional buckling and vibration problems of composite
 51 Euler-Bernoulli beams of arbitrarily shaped cross section. This method overcame the shortcoming of possible thin
 52 tube theory solution, which its utilization had been proven to be prohibitive even in thin-walled homogeneous sections.

53 In this paper, which is an extension of the authors' previous works [19-21], flexural-torsional coupled vibration of
 54 thin-walled composite box beams with arbitrary lay-ups under a constant axial force is presented. This model is based
 55 on the classical lamination theory, and accounts for all the structural coupling coming from the material anisotropy.
 56 Equations of motion are derived from the Hamilton's principle. A displacement-based one-dimensional finite element
 57 model is developed to solve the problem. Numerical results are obtained for thin-walled composite box beams to
 58 investigate the effects of axial force, fiber orientation and modulus ratio on the natural frequencies, load-frequency
 59 interaction curves and corresponding vibration mode shapes.

60 II. KINEMATICS

61 The theoretical developments presented in this paper require two sets of coordinate systems which are mutually
 62 interrelated. The first coordinate system is the orthogonal Cartesian coordinate system (x, y, z) , for which the x and
 63 y axes lie in the plane of the cross section and the z axis parallel to the longitudinal axis of the beam. The second
 64 coordinate system is the local plate coordinate (n, s, z) as shown in Fig.1, wherein the n axis is normal to the middle
 65 surface of a plate element, the s axis is tangent to the middle surface and is directed along the contour line of the
 66 cross section. The (n, s, z) and (x, y, z) coordinate systems are related through an angle of orientation θ as defined in
 67 Fig.1. Point P is called the pole axis, through which the axis parallel to the z axis is called the pole axis.

68 To derive the analytical model for a thin-walled composite beam, the following assumptions are made:

- 69 1. The contour of the thin wall does not deform in its own plane.
- 70 2. The linear shear strain $\bar{\gamma}_{sz}$ of the middle surface is to have the same distribution in the contour direction as it
 71 does in the St. Venant torsion in each element.
- 72 3. The Kirchhoff-Love assumption in classical plate theory remains valid for laminated composite thin-walled
 73 beams.
- 74 4. Each laminate is thin and perfectly bonded.
- 75 5. Local buckling is not considered.

76 According to assumption 1, the midsurface displacement components \bar{u}, \bar{v} at a point A in the contour coordinate
 77 system can be expressed in terms of a displacements U, V of the pole P in the x, y directions, respectively, and the
 78 rotation angle Φ about the pole axis,

$$\bar{u}(s, z) = U(z) \sin \theta(s) - V(z) \cos \theta(s) - \Phi(z)q(s) \quad (1a)$$

$$\bar{v}(s, z) = U(z) \cos \theta(s) + V(z) \sin \theta(s) + \Phi(z)r(s) \quad (1b)$$

79 These equations apply to the whole contour. The out-of-plane shell displacement \bar{w} can now be found from the
 80 assumption 2. For each element of middle surface, the shear strain become

$$\bar{\gamma}_{sz} = \frac{\partial \bar{v}}{\partial z} + \frac{\partial \bar{w}}{\partial s} = \Phi'(z) \frac{F(s)}{t(s)} \quad (2)$$

81 where $t(s)$ is thickness of contour box section, $F(s)$ is the St. Venant circuit shear flow.

82 After substituting for \bar{v} from Eq.(1) and considering the following geometric relations,

$$dx = ds \cos \theta \quad (3a)$$

$$dy = ds \sin \theta \quad (3b)$$

83 Eq.(2) can be integrated with respect to s from the origin to an arbitrary point on the contour,

$$\bar{w}(s, z) = W(z) - U'(z)x(s) - V'(z)y(s) - \Phi'(z)\omega(s) \quad (4)$$

84 where differentiation with respect to the axial coordinate z is denoted by primes (''); W represents the average axial
 85 displacement of the beam in the z direction; x and y are the coordinates of the contour in the (x, y, z) coordinate
 86 system; and ω is the so-called sectorial coordinate or warping function given by

$$\omega(s) = \int_{s_0}^s \left[r(s) - \frac{F(s)}{t(s)} \right] ds \quad (5a)$$

$$\oint_i \frac{F(s)}{t(s)} ds = 2A_i \quad i = 1, \dots, n \quad (5b)$$

87 where $r(s)$ is height of a triangle with the base ds ; A_i is the area circumscribed by the contour of the i circuit. The
 88 explicit forms of $\omega(s)$ and $F(s)$ for box section are given in Ref.[19].

89 The displacement components u, v, w representing the deformation of any generic point on the profile section are
 90 given with respect to the midsurface displacements $\bar{u}, \bar{v}, \bar{w}$ by the assumption 3.

$$u(s, z, n) = \bar{u}(s, z) \quad (6a)$$

$$v(s, z, n) = \bar{v}(s, z) - n \frac{\partial \bar{u}(s, z)}{\partial s} \quad (6b)$$

$$w(s, z, n) = \bar{w}(s, z) - n \frac{\partial \bar{u}(s, z)}{\partial z} \quad (6c)$$

91 The strains associated with the small-displacement theory of elasticity are given by

$$\epsilon_s = \bar{\epsilon}_s + n\bar{\kappa}_s \quad (7a)$$

$$\epsilon_z = \bar{\epsilon}_z + n\bar{\kappa}_z \quad (7b)$$

$$\gamma_{sz} = \bar{\gamma}_{sz} + n\bar{\kappa}_{sz} \quad (7c)$$

92 where

$$\bar{\epsilon}_s = \frac{\partial \bar{v}}{\partial s}; \quad \bar{\epsilon}_z = \frac{\partial \bar{w}}{\partial z} \quad (8a)$$

$$\bar{\kappa}_s = -\frac{\partial^2 \bar{u}}{\partial z^2}; \quad \bar{\kappa}_z = -\frac{\partial^2 \bar{u}}{\partial z^2}; \quad \bar{\kappa}_{sz} = -2\frac{\partial^2 \bar{u}}{\partial s \partial z} \quad (8b)$$

93 All the other strains are identically zero. In Eq.(8), $\bar{\epsilon}_s$ and $\bar{\kappa}_s$ are assumed to be zero. $\bar{\epsilon}_z$, $\bar{\kappa}_z$ and $\bar{\kappa}_{sz}$ are midsurface
94 axial strain and biaxial curvature of the shell, respectively. The above shell strains can be converted to beam strain
95 components by substituting Eqs.(1), (4) and (6) into Eq.(8) as

$$\bar{\epsilon}_z = \epsilon_z^\circ + x\kappa_y + y\kappa_x + \omega\kappa_\omega \quad (9a)$$

$$\bar{\kappa}_z = \kappa_y \sin \theta - \kappa_x \cos \theta - \kappa_\omega q \quad (9b)$$

$$\bar{\kappa}_{sz} = 2\bar{\chi}_{sz} = \kappa_{sz} \quad (9c)$$

96 where ϵ_z° , κ_x , κ_y , κ_ω and κ_{sz} are axial strain, biaxial curvatures in the x and y direction, warping curvature with
97 respect to the shear center, and twisting curvature in the beam, respectively defined as

$$\epsilon_z^\circ = W' \quad (10a)$$

$$\kappa_x = -V'' \quad (10b)$$

$$\kappa_y = -U'' \quad (10c)$$

$$\kappa_\omega = -\Phi'' \quad (10d)$$

$$\kappa_{sz} = 2\Phi' \quad (10e)$$

98 The resulting strains can be obtained from Eqs.(7) and (9) as

$$\epsilon_z = \epsilon_z^\circ + (x + n \sin \theta)\kappa_y + (y - n \cos \theta)\kappa_x + (\omega - nq)\kappa_\omega \quad (11a)$$

$$\gamma_{sz} = \left(n + \frac{F}{2t}\right)\kappa_{sz} \quad (11b)$$

99 III. VARIATIONAL FORMULATION

100 The total potential energy of the system can be stated, in its buckled shape, as

$$\Pi = \mathcal{U} + \mathcal{V} \quad (12)$$

101 where \mathcal{U} is the strain energy

$$\mathcal{U} = \frac{1}{2} \int_v (\sigma_z \epsilon_z + \sigma_{sz} \gamma_{sz}) dv \quad (13)$$

102 After substituting Eq.(11) into Eq.(13)

$$\mathcal{U} = \frac{1}{2} \int_v \left\{ \sigma_z \left[\epsilon_z^0 + (x + n \sin \theta) \kappa_y + (y - n \cos \theta) \kappa_x + (\omega - nq) \kappa_\omega \right] + \sigma_{sz} \left(n + \frac{F}{2t} \right) \kappa_{sz} \right\} dv \quad (14)$$

103 The variation of strain energy can be stated as

$$\delta \mathcal{U} = \int_0^l (N_z \delta \epsilon_z + M_y \delta \kappa_y + M_x \delta \kappa_x + M_\omega \delta \kappa_\omega + M_t \delta \kappa_{sz}) dz \quad (15)$$

104 where $N_z, M_x, M_y, M_\omega, M_t$ are axial force, bending moments in the x - and y -direction, warping moment (bimoment),

105 and torsional moment with respect to the centroid, respectively, defined by integrating over the cross-sectional area A

106 as

$$N_z = \int_A \sigma_z ds dn \quad (16a)$$

$$M_y = \int_A \sigma_z (x + n \sin \theta) ds dn \quad (16b)$$

$$M_x = \int_A \sigma_z (y - n \cos \theta) ds dn \quad (16c)$$

$$M_\omega = \int_A \sigma_z (\omega - nq) ds dn \quad (16d)$$

$$M_t = \int_A \sigma_{sz} \left(n + \frac{F}{2t} \right) ds dn \quad (16e)$$

107 The potential of in-plane loads \mathcal{V} due to transverse deflection

$$\mathcal{V} = \frac{1}{2} \int_v \bar{\sigma}_z^0 [(u')^2 + (v')^2] dv \quad (17)$$

108 where $\bar{\sigma}_z^0$ is the averaged constant in-plane edge axial stress, defined by $\bar{\sigma}_z^0 = P_0/A$. The variation of the potential of

109 in-plane loads at the centroid is expressed by substituting the assumed displacement field into Eq.(17) as

$$\begin{aligned} \delta \mathcal{V} = & \int_v \frac{P_0}{A} \left[U' \delta U' + V' \delta V' + (q^2 + r^2 + 2rn + n^2) \Phi' \delta \Phi' + (\Phi' \delta U' + U' \delta \Phi') [n \cos \theta - (y - y_p)] \right. \\ & \left. + (\Phi' \delta V' + V' \delta \Phi') [n \cos \theta + (x - x_p)] \right] dv \end{aligned} \quad (18)$$

110 The kinetic energy of the system is given by

$$\mathcal{T} = \frac{1}{2} \int_v \rho(\dot{u}^2 + \dot{v}^2 + \dot{w}^2) dv \quad (19)$$

111 where ρ is a density.

112 The variation of the kinetic energy is expressed by substituting the assumed displacement field into Eq.(19) as

$$\begin{aligned} \delta\mathcal{T} = \int_v \rho \left\{ \dot{U}\delta\dot{U} + \dot{V}\delta\dot{V} + \dot{W}\delta\dot{W} + (q^2 + r^2 + 2rn + n^2)\dot{\Phi}\delta\dot{\Phi} + (\dot{\Phi}\delta\dot{U} + \dot{U}\delta\dot{\Phi}) \left[n \cos\theta - (y - y_p) \right] \right. \\ \left. + (\dot{\Phi}\delta\dot{V} + \dot{V}\delta\dot{\Phi}) \left[n \cos\theta + (x - x_p) \right] \right\} dv \end{aligned} \quad (20)$$

113 In order to derive the equations of motion, Hamilton's principle is used

$$\delta \int_{t_1}^{t_2} (\mathcal{T} - \Pi) dt = 0 \quad (21)$$

114 Substituting Eqs.(15),(18) and (20) into Eq.(21), the following weak statement is obtained

$$\begin{aligned} 0 = \int_{t_1}^{t_2} \int_0^l \left\{ m_0 \dot{W} \delta \dot{W} + \left[m_0 \dot{U} + (m_c - m_y + m_0 y_p) \dot{\Phi} \right] \delta \dot{U} + \left[m_0 \dot{V} + (m_s + m_x - m_0 x_p) \dot{\Phi} \right] \delta \dot{V} \right. \\ + \left[(m_c - m_y + m_0 y_p) \dot{U} + (m_s + m_x - m_0 x_p) \dot{V} + (m_p + m_2 + 2m_\omega) \dot{\Phi} \right] \delta \dot{\Phi} \\ - \left[P_0 [\delta U'(U' + \Phi' y_p) + \delta V'(V' - \Phi' x_p) + \delta \Phi' (\Phi' \frac{I_p}{A} + U' y_p - V' x_p)] \right. \\ \left. - N_z \delta W' + M_y \delta U'' + M_x \delta V'' + M_\omega \delta \Phi'' - 2M_t \delta \Phi \right\} dz dt \end{aligned} \quad (22)$$

115 The explicit expressions of inertia coefficients for composite box section are given in Ref.[21].

116 IV. CONSTITUTIVE EQUATIONS

117 The constitutive equations of a k^{th} orthotropic lamina in the laminate co-ordinate system of section are given by

$$\begin{Bmatrix} \sigma_z \\ \sigma_{sz} \end{Bmatrix}^k = \begin{bmatrix} \bar{Q}_{11}^* & \bar{Q}_{16}^* \\ \bar{Q}_{16}^* & \bar{Q}_{66}^* \end{bmatrix}^k \begin{Bmatrix} \epsilon_z \\ \gamma_{sz} \end{Bmatrix} \quad (23)$$

118 where \bar{Q}_{ij}^* are transformed reduced stiffnesses. The transformed reduced stiffnesses can be calculated from the
119 transformed stiffnesses based on the plane stress assumption and plane strain assumption. More detailed explanation
120 can be found in Ref.[22]

121 The constitutive equations for bar forces and bar strains are obtained by using Eqs.(11), (16) and (23)

$$\begin{Bmatrix} N_z \\ M_y \\ M_x \\ M_\omega \\ M_t \end{Bmatrix} = \begin{bmatrix} E_{11} & E_{12} & E_{13} & E_{14} & E_{15} \\ & E_{22} & E_{23} & E_{24} & E_{25} \\ & & E_{33} & E_{34} & E_{35} \\ & & & E_{44} & E_{45} \\ \text{sym.} & & & & E_{55} \end{bmatrix} \begin{Bmatrix} \epsilon_z^\circ \\ \kappa_y \\ \kappa_x \\ \kappa_\omega \\ \kappa_{sz} \end{Bmatrix} \quad (24)$$

122 where E_{ij} are stiffnesses of thin-walled composite beams and given in Ref.[19].

123 V. GOVERNING EQUATIONS OF MOTION

124 The governing equations of motion of the present study can be derived by integrating the derivatives of the varied
125 quantities by parts and collecting the coefficients of $\delta W, \delta U, \delta V$ and $\delta \Phi$

$$N'_z = m_0 \ddot{W} \quad (25a)$$

$$M''_y + P_0(U'' + \Phi'' y_p) = m_0 \ddot{U} + (m_c - m_y + m_0 y_p) \ddot{\Phi} \quad (25b)$$

$$M''_x + P_0(V'' - \Phi'' x_p) = m_0 \ddot{V} + (m_s + m_x - m_0 x_p) \ddot{\Phi} \quad (25c)$$

$$\begin{aligned} M''_\omega + 2M'_t + P_0\left(\Phi'' \frac{I_p}{A} + U'' y_p - V'' x_p\right) &= (m_c - m_y + m_0 y_p) \ddot{U} \\ &+ (m_s + m_x - m_0 x_p) \ddot{V} + (m_p + m_2 + 2m_\omega) \ddot{\Phi} \end{aligned} \quad (25d)$$

126 The natural boundary conditions are of the form

$$\delta W : N_z = P_0 \quad (26a)$$

$$\delta U : M_y = M_y^0 \quad (26b)$$

$$\delta U' : M'_y = M_y'^0 \quad (26c)$$

$$\delta V : M_x = M_x^0 \quad (26d)$$

$$\delta V' : M'_x = M_x'^0 \quad (26e)$$

$$\delta \Phi : M'_\omega + 2M_t = M_\omega'^0 \quad (26f)$$

$$\delta \Phi' : M_\omega = M_\omega^0 \quad (26g)$$

127 where $P_0, M_y'^0, M_y^0, M_x'^0, M_x^0, M_\omega'^0$ and M_ω^0 are prescribed values.

128 Eq.(25) is most general form for flexural-torsional vibration of thin-walled composite beams under a constant axial
129 force, and the dependent variables, W, U, V and Φ are fully coupled. By substituting Eqs.(10) and (24) into Eq.(25),

130 the explicit form of governing equations of motion can be obtained. If all the coupling effects are neglected and
 131 the cross section is symmetrical with respect to both x - and the y -axes, Eq.(25) can be simplified to the uncoupled
 132 differential equations as

$$(EA)_{com}W'' = \rho A\ddot{W} \quad (27a)$$

$$-(EI_y)_{com}U^{iv} + P_0U'' = \rho A\ddot{U} \quad (27b)$$

$$-(EI_x)_{com}V^{iv} + P_0V'' = \rho A\ddot{V} \quad (27c)$$

$$-(EI_\omega)_{com}\Phi^{iv} + \left[(GJ)_{com} + P_0\frac{I_p}{A}\right]\Phi'' = \rho I_p\ddot{\Phi} \quad (27d)$$

133 From above equations, $(EA)_{com}$ represents axial rigidity, $(EI_x)_{com}$ and $(EI_y)_{com}$ represent flexural rigidities with
 134 respect to x - and y -axis, $(EI_\omega)_{com}$ represents warping rigidity, and $(GJ)_{com}$, represents torsional rigidity of thin-
 135 walled composite beams, respectively, written as

$$(EA)_{com} = E_{11} \quad (28a)$$

$$(EI_y)_{com} = E_{22} \quad (28b)$$

$$(EI_x)_{com} = E_{33} \quad (28c)$$

$$(EI_\omega)_{com} = E_{44} \quad (28d)$$

$$(GJ)_{com} = 4E_{55} \quad (28e)$$

136 It is well known that the three distinct load-frequency interaction curves corresponding to flexural buckling and
 137 natural frequencies in the x - and y - direction, and torsional buckling and natural frequency, respectively. They are
 138 given by the orthotropy solution for simply supported boundary conditions [23]

$$\omega_{xx_n} = \omega_{x_n} \sqrt{1 - \frac{P_0}{P_x}} \quad (29a)$$

$$\omega_{yy_n} = \omega_{y_n} \sqrt{1 - \frac{P_0}{P_y}} \quad (29b)$$

$$\omega_{\theta\theta_n} = \omega_{\theta_n} \sqrt{1 - \frac{P_0}{P_\theta}} \quad (29c)$$

139 where ω_{x_n} , ω_{y_n} and ω_{θ_n} are corresponding flexural natural frequencies in the x - and y -direction and torsional natural

140 frequency [4].

$$\omega_{x_n} = \frac{n^2\pi^2}{l^2} \sqrt{\frac{(EI_y)_{com}}{\rho A}} \quad (30a)$$

$$\omega_{y_n} = \frac{n^2\pi^2}{l^2} \sqrt{\frac{(EI_x)_{com}}{\rho A}} \quad (30b)$$

$$\omega_{\theta_n} = \frac{n\pi}{l} \sqrt{\frac{1}{\rho I_p} \left[\frac{n^2\pi^2}{l^2} (EI_\omega)_{com} + (GJ)_{com} \right]} \quad (30c)$$

141 and P_x, P_y and P_θ are also corresponding flexural buckling loads in the x - and y -direction and torsional buckling
142 load [5], respectively.

$$P_x = \frac{\pi^2 (EI_y)_{com}}{l^2} \quad (31a)$$

$$P_y = \frac{\pi^2 (EI_x)_{com}}{l^2} \quad (31b)$$

$$P_\theta = \frac{A}{I_p} \left[\frac{\pi^2 (EI_\omega)_{com}}{l^2} + (GJ)_{com} \right] \quad (31c)$$

143 VI. FINITE ELEMENT FORMULATION

144 The present theory for thin-walled composite beams described in the previous section was implemented via a
145 displacement based finite element method. The generalized displacements are expressed over each element as a linear
146 combination of the one-dimensional Lagrange interpolation function Ψ_j and Hermite-cubic interpolation function ψ_j
147 associated with node j and the nodal values

$$W = \sum_{j=1}^n w_j \Psi_j \quad (32a)$$

$$U = \sum_{j=1}^n u_j \psi_j \quad (32b)$$

$$V = \sum_{j=1}^n v_j \psi_j \quad (32c)$$

$$\Phi = \sum_{j=1}^n \phi_j \psi_j \quad (32d)$$

148 Substituting these expressions into the weak statement in Eq.(18), the finite element model of a typical element
149 can be expressed as the standard eigenvalue problem

$$([K] - P_0[G] - \omega^2[M])\{\Delta\} = \{0\} \quad (33)$$

150 where $[K], [G]$ and $[M]$ are the element stiffness matrix, the element geometric stiffness matrix and the element
151 mass matrix, respectively. The explicit forms of $[K], [G]$ and $[M]$ are given in Refs.[19-21].

152 In Eq.(33), $\{\Delta\}$ is the eigenvector of nodal displacements corresponding to an eigenvalue

$$\{\Delta\} = \{W \ U \ V \ \Phi\}^T \quad (34)$$

153 VII. NUMERICAL EXAMPLES

154 A thin-walled composite box beam with length $l = 8\text{m}$ is considered to investigate the effects of axial force, fiber
155 orientation and modulus ratio on the natural frequencies, load-frequency interaction curves and the corresponding
156 mode shapes. The geometry and stacking sequences of the box section are shown in Fig.2, and the following engineering
157 constants are used

$$E_1/E_2 = 25, G_{12}/E_2 = 0.6, \nu_{12} = 0.25 \quad (35)$$

158 For convenience, the following nondimensional axial force and natural frequency are used

$$\bar{P} = \frac{Pl^2}{b_1^3 t E_2} \quad (36a)$$

$$\bar{\omega} = \frac{\omega l^2}{b_1} \sqrt{\frac{\rho}{E_2}} \quad (36b)$$

159 The left and right webs are angle-ply laminates $[\theta/-\theta]$ and $[-\theta/\theta]$ and the flanges laminates are assumed to be
160 unidirectional, (Fig.2a). All the coupling stiffnesses are zero, but E_{25} does not vanish due to unsymmetric stacking
161 sequence of the webs. The lowest three natural frequencies with and without the effect of axial force are given in
162 Table I. The critical buckling loads and the natural frequencies without axial force agree completely with those of
163 previous papers [20,21], as expected. It can be shown from Table I that the change in the natural frequencies due
164 to axial force is significant for all fiber angles. It is noticed that the natural frequencies increase as the axial force
165 changes from compression ($\bar{P} = 0.5 \times P_{cr}$) to tension ($\bar{P} = -0.5 \times P_{cr}$) which reveals that the compressive force has
166 a softening effect on the natural frequencies while the tension force has a stiffening effect. The typical normal mode
167 shapes corresponding to the lowest three natural frequencies with fiber angle $\theta = 30^\circ$ for the case of a compressive
168 axial force ($\bar{P} = 0.5 \times P_{cr}$) are illustrated in Figs.3-5. The mode shapes for other cases of axial force ($\bar{P} = 0$ and
169 $\bar{P} = -0.5 \times P_{cr}$) are similar to the corresponding ones for the case of axial force ($\bar{P} = 0.5 \times P_{cr}$) and are not
170 plotted, although there is a little difference between them. The lowest three interaction diagrams with the fiber
171 angle $\theta = 0^\circ$ and 30° obtained by finite element analysis and the orthotropy solution, which neglects the coupling
172 effects of E_{25} from Eqs.(29a)-(29c) are plotted in Figs.6 and 7. For unidirectional fiber direction (Fig.6), the smallest

173 curve exactly corresponds to the first flexural in x -direction and the larger ones correspond to the first flexural in
 174 y -direction and the second flexural in x -direction of the orthotropy solution, respectively. However, as the fiber angle
 175 and axial compressive force increase, this order is changing. It can be explained partly by the interaction diagram
 176 between flexural buckling and natural frequency with the fiber angle $\theta = 30^\circ$ in Fig.7. When the beam is subjected
 177 to small axial compressive force, the vibration mode 1 and 2 are the first flexural x - and y -direction (Figs.3 and 4).
 178 Thus, the orthotropy solution and the finite element analysis are identical. It is from Fig.5 that the vibration mode 3
 179 exhibits double coupling (the second flexural mode in x -direction and torsional mode). Due to the small coupling
 180 stiffnesses E_{25} , this mode becomes predominantly the second flexural x -direction mode, with a little contribution from
 181 torsion. Therefore, the results by the finite element analysis ($w_3 - P_3$) and orthotropy solution ($w_{x_2} - P_{x_2}$) are nearly
 182 identical in Fig.7. It is indicated that the simple orthotropy solution is sufficiently accurate for this stacking sequence.
 183 Characteristic of load-frequency interaction curves is that the value of the axial force for which the natural frequency
 184 vanishes constitutes the critical buckling load. Thus, for $\theta = 30^\circ$, the first flexural buckling in minor axis occurs at
 185 $\bar{P} = 13.88$. Therefore, the lowest branch vanishes when \bar{P} is slightly over this value. As axial force \bar{P} increases, two
 186 interaction curves $w_{y_1} - P_{y_1}$ and $w_{x_2} - P_{x_2}$ intersect at $\bar{P} = 48.10$, thus, after this value, vibration mode 2 and 3
 187 change each other. Finally, the second and third branch will also disappear when \bar{P} is slightly over 54.53 and 73.16,
 188 respectively. Figs.6 and 7 explain the duality between flexural buckling and natural frequency. A comprehensive three
 189 dimensional interaction diagram of natural frequency, axial compression and fiber angle is plotted in Fig.8. Three
 190 groups of curves are observed. The smallest group is for the first flexural mode in x -direction and the larger ones are
 191 for the first flexural mode in y -direction and flexural-torsional coupled mode, respectively.

192 The next example is the same as before except that in this case, the top flange and the left web laminates are $[\theta_2]$,
 193 while the bottom flange and right web laminates are unidirectional, (Fig.2b). For this lay-up, the coupling stiffnesses
 194 $E_{14}, E_{15}, E_{23}, E_{25}$ and E_{35} become no more negligibly small. Major effects of compressive axial force on the natural
 195 frequencies are again seen in Table II. Three dimensional interaction diagram between flexural-torsional buckling and
 196 natural frequency with respect to the fiber angle change is shown in Fig.9. Similar phenomena as the previous example
 197 can be observed except that in this case all three groups are flexural-torsional coupled mode. The interaction diagram
 198 between flexural-torsional buckling and natural frequency by the finite element analysis and orthotropy solution with
 199 the fiber angle $\theta = 30^\circ$ and 60° are displayed in in Figs.10 and 11. It can be remarked again that the natural
 200 frequencies decrease with the increase of compressive axial forces, and the decrease becomes more quickly when axial
 201 forces are close to flexural-torsional buckling loads. For $\theta = 60^\circ$, at about $\bar{P} = 7.92, 31.28$ and 47.11 , respectively, the

202 natural frequencies become zero which implies that at these loads, flexural-torsional bucklings occur as a degenerate
 203 case of natural vibration at zero frequency. As the fiber angle and compressive axial force increases, the orthotropy
 204 solution and the finite element analysis solution show significantly discrepancy (Figs.10 and 11). The typical normal
 205 mode shapes corresponding to the lowest three natural frequencies with fiber angle $\theta = 60^\circ$ for the case of compressive
 206 axial force ($\bar{P} = 0.5 \times P_{cr}$) are illustrated in Figs.12-14. Relative measures of flexural displacements and torsional
 207 rotation show that all the modes are triply coupled mode (flexural mode in the x - and y -directions and torsional
 208 mode). That is, the orthotropy solution is no longer valid for unsymmetrically laminated beams, and triply coupled
 209 flexural-torsional vibration should be considered even for a doubly symmetric cross-section.

210 Finally, the effects of modulus ratio (E_1/E_2) on the first five natural frequencies of a cantilever thin-walled composite
 211 beam under a compressive axial force ($\bar{P} = 0.5 \times P_{cr}$) are investigated. The stacking sequence of the flanges and webs
 212 are $[0/90]_s$, (Fig.2c). For this lay-up, all the coupling stiffnesses vanish and thus, the three distinct vibration mode,
 213 flexural vibration in the x - and y -direction and torsional vibration are identified. It is observed from Fig.15 that the
 214 natural frequencies ω_{xx_1} , ω_{yy_1} , ω_{xx_2} and ω_{yy_2} increase with increasing orthotropy (E_1/E_2). However, torsional natural
 215 frequency is almost invariant and well above the other three types of natural frequencies, i.e. ω_{xx_1} , ω_{yy_1} and ω_{xx_2} .
 216 It can be explained from Eqs.(29c) and (30c) that torsional frequency is dominated by torsional rigidity rather than
 217 warping rigidity. Moreover, effects of warping is negligibly small for box section. As ratio of (E_1/E_2) increases, the
 218 order of the second flexural mode in the y -direction, the torsional mode change each other.

219 VIII. CONCLUDING REMARKS

220 An analytical model is developed to study the flexural-torsional coupled vibration of thin-walled composite beams
 221 with arbitrary lay-ups under a constant axial force. This model is capable of predicting accurately the natural
 222 frequencies and load-frequency interaction curves as well as corresponding vibration mode shapes for various. To
 223 formulate the problem, a one-dimensional displacement-based finite element method is employed. All of the possible
 224 vibration modes including the flexural mode in the x - and y -direction and the torsional mode, and fully coupled
 225 flexural-torsional mode are included in the analysis. The present model is found to be appropriate and efficient in
 226 analyzing free vibration problem of thin-walled composite beams under a constant axial force.
