57 **1.0 Introduction**

58 Worldwide, governments are struggling to ensure their transport assets can adapt to external
59 disturbances (in this case, climate change-related events), especially since the Coronavirus-
60 2019 (COVID-19) outbreak (Sircar *et al.*, 2013; Spaans and Waterhout, 2017; Pregnolato *et*
61 *al.*, 2017; Love *et al.*, 2018a,b; Van der Merwe and Van der Waldt, 2018; Zhang and Li, 2018;
62 Love *et al.*, 2020; Ton *et al.*, 2020). In 2009/2010 and 2010/2011, heavy snowfalls led to travel
63 chaos throughout the United Kingdom (UK), adversely disrupting airports, railways and road
64 networks. In 2019 England was subjected to torrential downpours, which resulted in 73 flood
65 warnings and a disrupted transport network, especially its Northern Rail services. Additionally,
66 London’s Liverpool Street station was flooded, causing severe track circuit failures and
67 platform closures. Adverse weather conditions have become the norm in the UK and are now
68 anticipated, though many uncertainties reside around such events’ severity. In response to
69 increasingly adverse environmental events, the UK Government has developed a dedicated
70 ‘Sector Resilience Plan’ to mitigate its infrastructure assets’ vulnerability and improve its
71 resilience (Cabinet Office, 2019).

72

73 Resilience primarily relates to how infrastructure can positively withstand, absorb and respond
74 to changing conditions (Bosher and Dainty, 2011; NCCARF, 2013; Hughes and Healy, 2014).
75 Enabling resilient infrastructure is a sophisticated and systematic process, which integrates
76 engineering, technical and managerial elements over an asset’s life-cycle (Desouza and Flanery,
77 2013; Love *et al.*, 2021). Thus, the underlying dynamics of infrastructure resilience are
78 diversified no more so than the capabilities such as the collective skills, abilities and expertise
79 of critical organisations, particularly governments, involved with the delivery of the assets
80 (Bosher *et al.*, 2009; Hughes and Healy, 2014; Liu *et al.*, 2019). To this end, an organisation’s

81 capability refers to its ability to perform a coordinated set of tasks, utilising its resources to
82 achieve a particular end result (Helfat and Peteraf, 2003: p.999).

83

84 Organisational capabilities are intangible assets and are “an outcome of investment in staffing,
85 training, compensation, communication and other human resource areas” (Smallwood and
86 Ulrich, 2004, p.119). They are also interdependent assets that comprise technical and social
87 components and emerge when competencies and abilities are combined. There is no “magic
88 list of capabilities” appropriate for governments to provide the intangible value needed to
89 ensure asset resilience (Smallwood and Ulrich, 2004, p.119). Despite their importance, there is
90 limited knowledge about the core capabilities required to underpin and enact a resilience
91 strategy. Lamenting this concern, the Cabinet Office (2017) in the UK acknowledged that a
92 lack of knowledge and understanding of organisational capabilities has contributed to its
93 inability to assess risk and uncertainty. Consequently, transport assets have performed poorly
94 as their fragility to adverse weather conditions has come to the fore (House of Commons, 2019;
95 Department for Transport, 2017; 2020).

96

97 While Cabinet Office (2017) in the UK has been cognisant of its inadequate organisational
98 capabilities to provide resilient infrastructure and has put in place policy initiatives to address
99 this issue, there remains limited research examining how they can be better identified and
100 developed. This paper seeks to fill this void in knowledge and thus addresses the following
101 research questions: (1) *How do government organisational capabilities interact with one*
102 *another to determine the resilience of transport projects?* and (2) *What is the best way to*
103 *manage these organisational capabilities to aid a resilience strategy?* Understanding the
104 interdependency between capabilities and identifying critical needs is needed to effectively

105 manage them and enable governments to establish a pathway to develop practical actions for
106 future improvement.

107

108 The paper commences with a review of the transport infrastructure resilience literature to
109 provide a contextual backdrop for the research (Section 2). Then, the research method used to
110 form the basis of the study's line of inquiry is presented (Section 3). Next, case studies from
111 the UK are used to address the proposed research questions (Section 4). A conceptual
112 framework for managing the organisational capabilities needed to ensure a transport asset's
113 resilience (Section 5) and its implications for research are then presented (Section 6). Finally,
114 the paper's conclusions are presented (Section 7).

115

116 **2.0 Transport Infrastructure Resilience**

117 The literature is replete with studies that have examined transport resilience (Love *et al.*, 2021).
118 Nonetheless, when transport networks are disrupted and/or damaged, the socio-economic
119 wellbeing of an economy can be adversely impacted (Cox *et al.*, 2011; Reggiani, 2013; Hughes
120 and Healy, 2014; Reggiani *et al.*, 2015; Wan *et al.*, 2017; Love *et al.*, 2018b; Ton *et al.*, 2020).
121 However, such impacts can be significantly minimised if the infrastructure assets are designed,
122 constructed, operated and maintained to adapt and respond to unexpected changes and effects
123 imposed on them (Love *et al.*, 2017; Zhang and Li, 2018).

124

125 The epistemology of resilience is underpinned by four questions: (1) resilience of what? (2)
126 resilience to what? (3) resilience for whom? and (4) how to be resilient (Vale, 2014; Chmutin
127 *et al.*, 2016). While no standard definition of resilience prevails, within the context of
128 infrastructure, four core elements have been identified in terms of an asset's ability to: (1)
129 predict and resist impacts; (2) absorb and accommodate stress and remain functional; (3) be

130 self-organised; and (4) learn, change and adapt (Davoudi, 2012; Thayaparan *et al.*, 2016; Wan
131 *et al.*, 2017). A recurring theme of resilience, spurred on by calls to respond to global climate
132 change, is its ability to accommodate environmental changes (Bruneau *et al.*, 2003; Boshier and
133 Dainty, 2011; Emmanuel and Krüger, 2012; Sircar *et al.* 2013; Balsas, 2014; Spaans and
134 Waterhout, 2017).

135

136 The advent of major terrorist incidents has intensified the interest in transport system resilience
137 (Bruyelle *et al.*, 2014). Emerging from Cox *et al.*'s (2011) research into the 2005 London
138 bombings were a series of operational metrics that sought to determine a passenger transport
139 system's resilience to terrorism based on its vulnerability, flexibility and resource availability
140 to cope with a terrorist attack or natural disaster. Continuing with the theme of underground
141 rail and buses, Jin *et al.* (2014) focused on developing an integrated multi-modal transport
142 network to improve a system's ability to adapt to increasing population and urban density. In
143 contrast, Venkittaraman and Banerjee (2013) examined the resilience of existing bridges to
144 natural hazards such as seismic activity by taking an ex-post perspective. They identified that
145 there is a need for bridges to be retrofitted to accommodate the likelihood of earthquakes.
146 Similarly, Becker and Caldwell (2015) adopted an *ex-ante* approach by soliciting stakeholders'
147 views to design and develop strategies to ensure a seaport's resilience.

148

149 **2.1 Organisational Capability and Resilience**

150 An organisation's capability refers to the capacity and resources that enable business functions
151 such as strategic planning, leadership, systems and procedures, human resources, innovation,
152 and network coordination to enact a strategy (Grant, 1991; Teece, 2007; Inan and Bititci, 2015).

153

154 Since the 1990s, there have been a wealth of studies that have sought to categorise
155 organisational capabilities and to identify how they impact business performance (Amit and
156 Schoemaker, 1993; Collis, 1994; Teece *et al.*, 1997; Winter, 2003; Zahra *et al.*, 2006),
157 Ambrosini *et al.*, 2009; Saunila *et al.*, 2014; Raffoni *et al.*, 2018; Khalil and Belitski, 2020).
158 Emerging from these studies is the role that stakeholders, regularly governments and
159 construction contractors, play in identifying the critical needs to construct resilient
160 infrastructure assets (Shaw *et al.*, 2019).

161
162 Table 1 presents the key studies conducted over the past decade investigating resilience from
163 an organisational capability perspective. A detailed examination of the literature reveals a
164 paucity of research examining the interdependency of organisational capabilities and how they
165 can be managed to ensure resilient transport systems (Blake *et al.*, 2019). Thus, acquiring an
166 understanding of how capabilities interact with one another can help policy-makers develop a
167 resilience strategy that can be used to *future-proof* their transport assets. That is, to be better
168 positioned to anticipate future events, changes and needs or uses to prepare appropriately,
169 minimize impact and capitalise on opportunities (Masood *et al.*, 2015; Love *et al.*, 2018a).

170

171 **3.0 Research Approach**

172 This study aims to develop new knowledge for managing transport infrastructure resilience
173 from a government's organisational capability perspective. An illustrative case study approach
174 (Gerring, 2006), which draws on the grey literature, is used to address the research questions
175 that have been proposed. The grey literature is defined as sources that are not formally
176 published in books and journals but are found in technical reports, pre-prints, the media, and
177 the like (Schöpfel and Farace, 2010). The use of grey literature to examine policy-related
178 matters is deemed a valid inquiry line (Søndergaard *et al.*, 2003).

179 A total of seven cases have been selected, which were significantly impacted by natural hazards
 180 in the UK (Table 2). Additionally, the cases are representative examples that the UK
 181 Government has used to demonstrate the need to ensure infrastructure resilience in the future
 182 (Department of Transport, 2014; Cabinet Office, 2017; Greater London Authority, 2019).

183

184 Table 1. Key studies investigating organisational capabilities and resilience within governments

Organisational Abilities	Research Targets	Authors
Strategies and stakeholder management	Entire built environment	Bosher <i>et al.</i> (2009)
Stakeholder and supply chain management	Entire infrastructure system	Steward <i>et al.</i> (2009)
Governance strategies	Communication systems	Carmeli and Markman (2011)
Workforce management	Entire infrastructure system	Santos <i>et al.</i> (2014)
Decision-making ability	Transport	Giezen <i>et al.</i> (2015)
Governance and empowerment in decision making	Community	Fan (2015)
Collaborating and networking, awareness and committing, learning, training and preparedness	City	Gimenez <i>et al.</i> (2017)
Performance management/measurement	Transport	Loo and Leung (2017)
Leadership, staff engagement, decision making, situation awareness and strategic planning	Entire built environment	Sapeciay <i>et al.</i> (2017)
Community engagement, leadership, finance, organisational structure and human resources	City	Van der Merve and Van der Waldt (2018)
Information management	Transport	Blake <i>et al.</i> (2019)
Governance	Community	Lee (2019)
Planning and resource management	Ports	Shaw <i>et al.</i> (2019)

185

186 Table 2. The transport assets/systems selected for case studies

Transport Assets/Systems	Documentary Sources
Motorway Network (e.g., M1, M4, M5, M18, M40, M50 and M54)	Department for Transport (2014)
A390 (road) at Cornwall	Department for Transport (2014) and Cornwall Council (2019)
London Gatwick Airport	Department for Transport (2014), McMillan (2014) and BBC (2019)
A303 (trunk road) at Deptford	Department for Transport (2014) and UK Parliament (2014)
Wokingham Borough Road System	Department for Transport (2014) and Cabinet Office (2017)

187

188 The research questions aim to determine how a government's capabilities can systematically
189 develop a framework to assist policy-makers in formulating a resilience strategy.

190

191 Social Network Analysis (SNA) was utilised to analyse the collected data from various
192 documentary sources identified in Table 2. The concept of SNA is a by-product of graph theory
193 and can be used to: (1) systematically map the interdependencies between the individuals and
194 their activities; (2) empirically interpret how such relationships can impact a network; and (3)
195 prioritise the key 'activities' needed to be focused for management and improvement using the
196 betweenness and closeness centralities (Otte and Rousseau, 2002). The robustness of SNA
197 presents itself as an appropriate technique to address the paper's research questions.

198

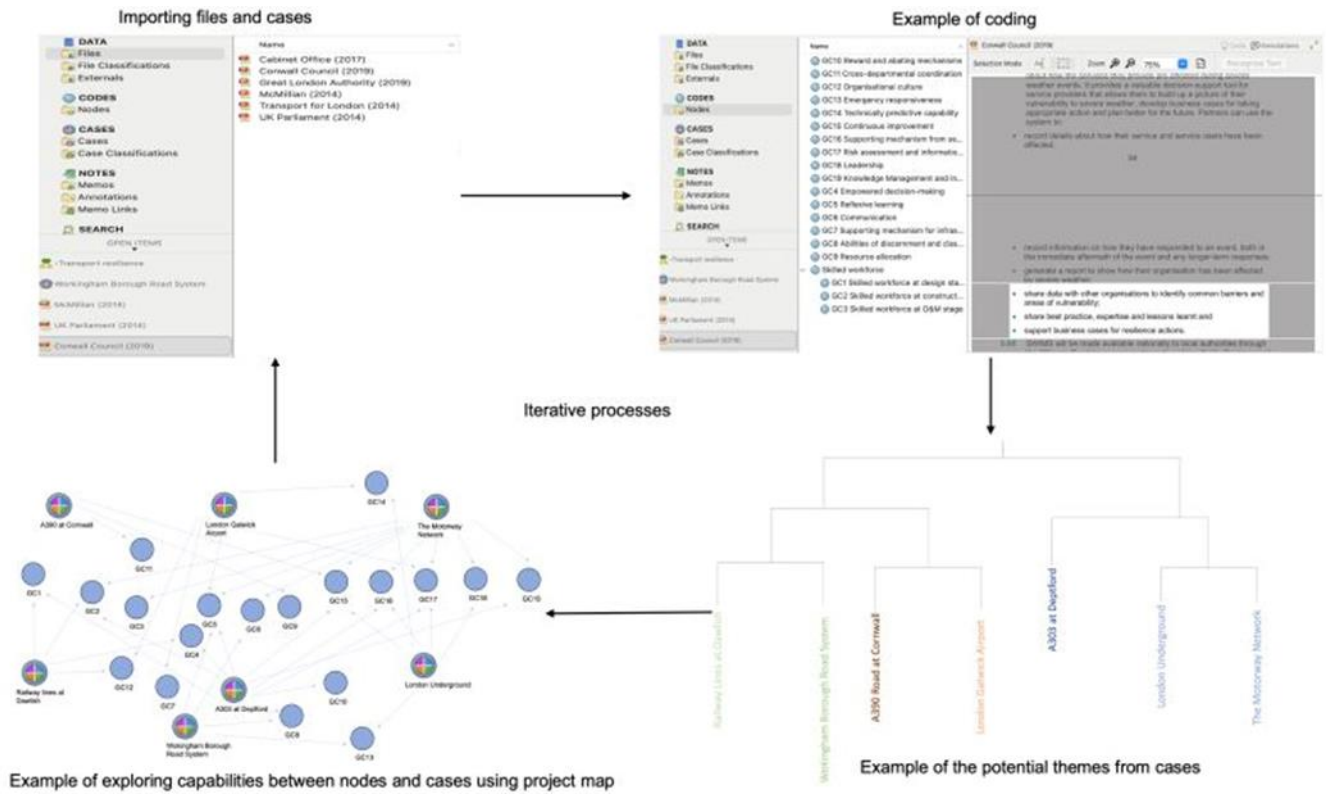

199 Previous studies have demonstrated that SNA is an effective technique to identify complex
200 network relationships in infrastructure projects (Zheng *et al.*, 2016; Herrera *et al.*, 2020; Wang
201 *et al.*, 2021). For instance, Herrera *et al.* (2019) utilised SNA to understand how a design team's
202 performance affected the quality of project outputs in construction. Contrastingly, Wang *et al.*
203 (2021) used SNA to identify the transmission patterns and underlying dynamics determining
204 the performance of Public-Private Partnerships (PPPs).

205

206 A series of 'points' (nodes) and 'lines' (edges) depict individuals' social structure within SNA
207 (Scott, 1988; Otte and Rousseau, 2002). While points represent the observed individuals, lines
208 visualise their interactions. Data acquired from the documentary sources presented in Table 2
209 was inputted into NVivo 12 to derive and analyse the point and edges of the government's

210 capabilities and interdependencies (Figure 1). Gephi was then adopted to construct an SNA to
 211 visualise the identified points and edges for further quantitative analysis.

212

213 Example of exploring capabilities between nodes and cases using project map

214 Example of the potential themes from cases

215 Figure 1. Process of data coding with NVivo

216

217 Two quantitative metrics, the ‘betweenness’ (Eq.1) and ‘closeness’ (Eq.2) centralities form the
 218 core of SNA and can be expressed as:

219

$$C_B(v) = \sum_{s \neq v \neq t} \frac{\sigma_{st}(v)}{\sigma_{st}} \quad [\text{Eq.1}]$$

220

$$C_c(v) = \sum_{\omega \in G} \frac{1}{d(v, \omega)} \quad [\text{Eq.2}]$$

221

222 Where σ_{st} represents the number of the shortest paths with s and t as their end vertices. At the
 223 same time $\sigma_{st}(v)$ is the number of such paths above, including vertex v . The ‘betweenness’
 224 centrality describes the frequency of a node that appears on the shortest path between nodes in

225 the network (Freeman, 1978). Similarly, the ‘closeness’ centrality is the average distance from
226 a given starting node to all others in a network (Borgatti, 1995). Thus, it is used to indicate how
227 close a node is to another one.

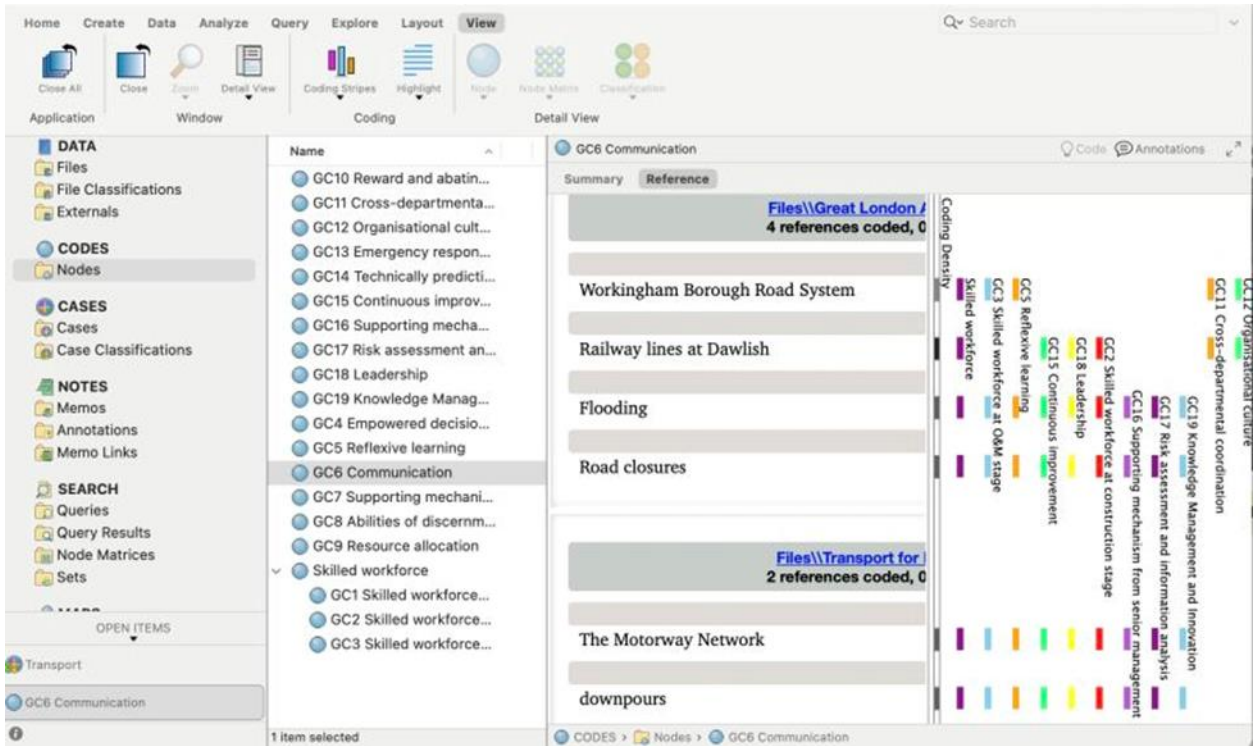

228

229 **4.0 Data Analysis**

230 As identified in Table 2, seven cases were used to examine the UK government’s capabilities
231 contribution to implementing an asset resilience strategy. As previously mentioned, the cases
232 were subjected to severe impacts due to extreme weather events (Table 3). For example, in July
233 2007, the road network comprising several critical motorways, including the M1, M4, M5,
234 M18, M25, M40 and M54, was adversely affected by closures resulting from unprecedented
235 downpours. Similarly, the electrical switchgear serving the North Terminal of London Gatwick
236 Airport was inundated by the flooding, which caused a cloudburst in December 2013.

237

238 Over the last five years, the UK Government has undertaken several investigations (presented
239 in Table 2) to determine the issues that have contributed to the poor resilience of their assets to
240 extreme weather events. We inputted the reports into NVivo 12 to code the data (Figure 2). We
241 then identified the organisational capabilities influencing the government’s inability to ensure
242 an asset’s resilience, as noted in Figure 3.

243

244 Figure 2. Coding for categorising the UK Government’s capabilities in determining resilience

245

246

247 *Adapted from: Department for Transport (2014), McMillian (2014), UK Parliament (2014), Cabinet*
 248 *Office (2017) Cornwall Council (2019) and Greater London Authority (2019)*

249 Figure 3. Government's capabilities in determining asset resilience

250

251 Serial codes were then assigned to the identified capabilities (presented in Figure 3) so that
 252 further analysis could be undertaken (Table 3). As illustrated by Figure 1, thematic analysis
 253 was then performed using NVivo 12. Then, 'Queries' using the 'Search' function were run to
 254 map the identified capabilities (Figure 3) with each transport case. The mapping results are
 255 presented in Table 4.

256

Table 3. Description for the capabilities being observed

Codes	Identified Capabilities	Definitions
GC1	Skilled workforce at design stage	The workforce of governmental departments that engage in the delivery of the transport projects
GC2	Skilled workforce at construction stage	
GC3	Skilled workforce at operation and maintenance stage	
GC4	Empowered decision-making	The power delegated to the teams or groups responsible for operating transport assets so that they can make decisions more efficiently when disasters/crisis happen
GC5	Reflexive learning	The learning mechanism of government for reflecting and capturing lessons learnt for organisational development
GC6	Communication	The communications between different departments in the government for works or actions initiated for enabling and/or ensuring resilience
GC7	Supporting mechanism for infrastructure system operations	The mechanisms across the departments of the government to support the operations of transport assets (i.e., the resilience planning workshops organised by the Department for Transport)
GC8	Abilities of discernment and classification	The organisation's ability in justifying and classifying the actions and/or initiatives essential for maintaining critical services during extreme weather
GC9	Resource allocation	The allocation of resources that are useful for developing, operating and maintaining the transport assets
GC10	Reward and abating mechanisms	The mechanisms placed for rewarding or abating the government's authorities that can or cannot address resilience in the delivery of transport assets
GC11	Cross-departmental coordination	The coordination across the departments within the government when a crisis occurs
GC12	Organisational culture	The organisational culture of resilience
GC13	Emergency responsiveness	The availability of practical guidance or procedure (i.e., the Local Resilience Fora and Strategic Co-ordinating Groups) in responding to an emergent situation (i.e., extreme weather incidents)
GC14	Technically predictive capability	The technical abilities of the government (e.g., systems, techniques and technologies) in effectively forecasting the risks (i.e., natural hazards) impacting the assets

GC15	Continuous improvement	The investment and efforts spent for continuously improving the practice in delivering resilient transport assets
GC16	Supporting mechanism from senior management	Effective and efficient supports from the government's top management for improving the practice in building resilient assets.
GC17	Risk assessment and information analysis	Climate Change Risk Assessment and the analysis of information collected from transport systems, such as the signalling and customer information systems.
GC18	Leadership	The styles of the leadership of the public authorities handling the delivery and operations of the assets
GC19	Knowledge Management and Innovation	The systems for managing the knowledge and innovation (i.e., training system) essential for enabling and ensuring resilience

272 **4.1 Findings**

273 Based on the data collected from various sources and the coding above, we generated a network
274 presented in Figure 4 using the Gephi 0.9.2 software package. The nodes connected by multiple
275 edges in the developed network represent the UK government's organisational capabilities,
276 which align with Figure 3. As there are both unidirectional ($A \rightarrow B$) and bidirectional ($A \rightarrow B$
277 and $B \rightarrow A$) links, the directed graph is chosen at the outset (Herrera *et al.*, 2020).

278

279 The network developed in Figure 4 comprises several nodes and edges relating to transport
280 resilience. The network contains 19 governmental capabilities illustrated in Figure 3, connected
281 by 245 unidirectional and bidirectional links. Overall, the graph density of the constructed SNA
282 model is 0.716 out of 1. The relevant degree is 12.895 on average, indicating a relatively high
283 degree of the observed capabilities, represented by the number of links connected to a node.
284 As the network was constructed from the data of real-world transport assets, the systematic
285 interactions between organisational capabilities and resilience provide a sound basis for
286 developing a framework for policy development.

287

288

289 Figure 4. SNA of the government's capabilities determining the assets' resilience ¹

290

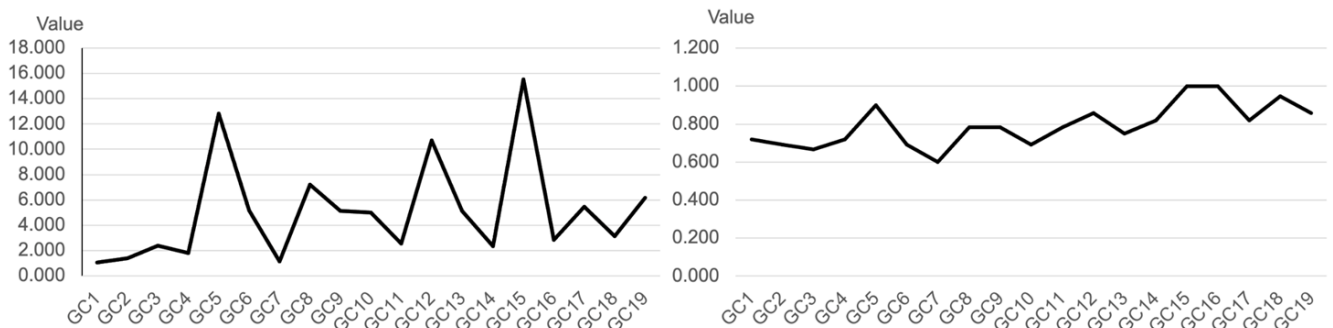

291 The size of the nodes in a network represents different levels of importance of the individuals
 292 being observed. In this case, a larger node denotes a higher level of an individual's impact on
 293 the network. It can be seen from Figure 4 that the size of nodes in the network varies, implying
 294 that their effects on the resilience for each case are different.

295

296 Based on the betweenness centrality (left panel of Figure 5), the top three capabilities that
 297 determine the resilience of the transport assets are: (1) 'continuous improvement' (15.546),
 298 'Reflexive learning' (a mechanism); (12.834); and (3) 'organisational culture' (10.683). The

¹ There are different layouts of network based on the types of metrics. This graph is visualised through degree.

299 betweenness centrality indicates which nodes are ‘bridges’ within the network (Disney, 2020).
 300 As addressed above, betweenness centrality indicates which ‘nodes’ are the ‘bridges’ between
 301 nodes within a network. When a node has a higher betweenness centrality, it is viewed as a
 302 ‘hub’ that transmits the influences of other nodes on the network.
 303
 304 In terms of closeness centrality² (right-hand panel of Figure 5), it can be seen that the
 305 ‘supporting mechanism from top management’ (1.000), ‘Reflexive learning’ (1.000) and
 306 ‘leadership’ (0.947) are the ‘shortest’ distances to all other nodes in the network. Therefore,
 307 the nodes with high closeness centrality are those ‘factors’ that dominate the network and can
 308 influence the entire network more significantly and efficiently than others. Put simply, the
 309 capabilities such as ‘supporting mechanism from top management, ‘Reflexive learning’ and
 310 ‘leadership’ are standing in the ‘best position’ to influence the resilience of a transport
 311 infrastructure system) (Disney, 2020).

312

313 Figure 5. Distribution of the government’s capabilities in determining transport resilience

314

315 **5.0 Managerial Framework**

316 The UK government has been confronted with an array of challenges in its quest to ensure it
 317 can provide the organisational capabilities needed to ensure its transport assets’ resilience.

318 However, the process of enhancing transport resilience from the perspective of organisational

² A measure showing the degree of the individuals' closeness to others, the variables,

319 capability is ambiguous. The SNA can be used to examine the interactive impacts of the
320 individual organisational capabilities on the resilience of a transport network. In the cases
321 above, the SNA modelling has identified and visualised the patterns about how the: (1)
322 capabilities interacted with each other in determining transport resilience; and (2) key ‘actors’
323 transmit the impacts of other factors within the network. Accordingly, the SNA findings from
324 the case studies are significant as they enable an understanding of the key capabilities that the
325 government needs to improve its ability to enact an infrastructure resilience strategy.

326

327 According to the betweenness centrality, the empirical evidence suggests that ‘organisational
328 culture’, ‘reflexive learning’ and ‘continuous improvement’ act as bridges to enable resilience.
329 Other capabilities, including the ‘supporting mechanism from top management’, ‘reflexive
330 learning’ and ‘leadership’, also influence resilience as indicated by the closeness centrality
331 measure. Naturally, support from the top management is needed for enhancing resilience. For
332 example, the UK’s Cabinet Office (2021) has developed a national resilience strategy to help
333 “understand our vulnerabilities, pre-empt challenges before they arise, ensure we are prepared
334 for them, and mitigate the impacts. Then, when events do occur, we should be ready to
335 withstand and recover.” (p.12)

336

337 Additionally, a robust learning mechanism provides organisation’s (i.e., governments) with an
338 ability to capture well and reflect the issues of their businesses, enabling them to actively
339 engage in continuous improvement and address a transport asset’s vulnerability (Elliott, 2020).
340 Notably, both the betweenness and closeness centralities of ‘Reflexive Learning’ are ranked
341 the highest by the SNA. This ranking suggests that the government’s learning mechanism is an
342 efficient capability enabling resilience and is a significant ‘hub’ for transmitting the impacts of
343 other capabilities on the entire network. Based on the findings above, a managerial framework

344 is developed to determine the needs and actions required by the government to ensure they
345 have the organisational capability to deliver resilient transport assets.

346

347 The provision of resilience is a challenge, but with top management support and leadership,
348 which is transformational, governments will be well-positioned to enact a process of innovation
349 and continuous improvement (Figure 6) (Bednall *et al.*, 2018). The reason for doing so is that
350 a significant relationship exists between leadership style and organisational changes in an
351 organisation (Matzler *et al.*, 2008). For instance, transformational leadership is essential for
352 business and project success, boosting organisational and technological innovation (Aga *et al.*,
353 2016).

354

355 Technological innovation and development play a critical role in driving asset management
356 forward (Baker *et al.*, 2019), which is pivotal for delivering resilient transport infrastructure
357 assets (Love *et al.*, 2021). In addition, transformational leadership is often required to: (1)
358 manage technology-enabled change to improve business processes and a transport asset's
359 adaptability and resilience; and (2) generate vision to guide the change process changes
360 (Bednall *et al.*, 2018). It is proffered that government departments that oversee the
361 procurement, management and operation of transport assets should have in place a programme
362 to develop the skills of their leaders so that they have an: (1) awareness of the increasing natural
363 and human-made impacts on their assets; (2) ability to predict future impacts and a create a
364 strategy to implement the change needed to accommodate natural and human-made impacts;
365 and (3) interpersonal capability to develop a business network (Trevor and Hill, 2012;
366 Hamdani, 2018).

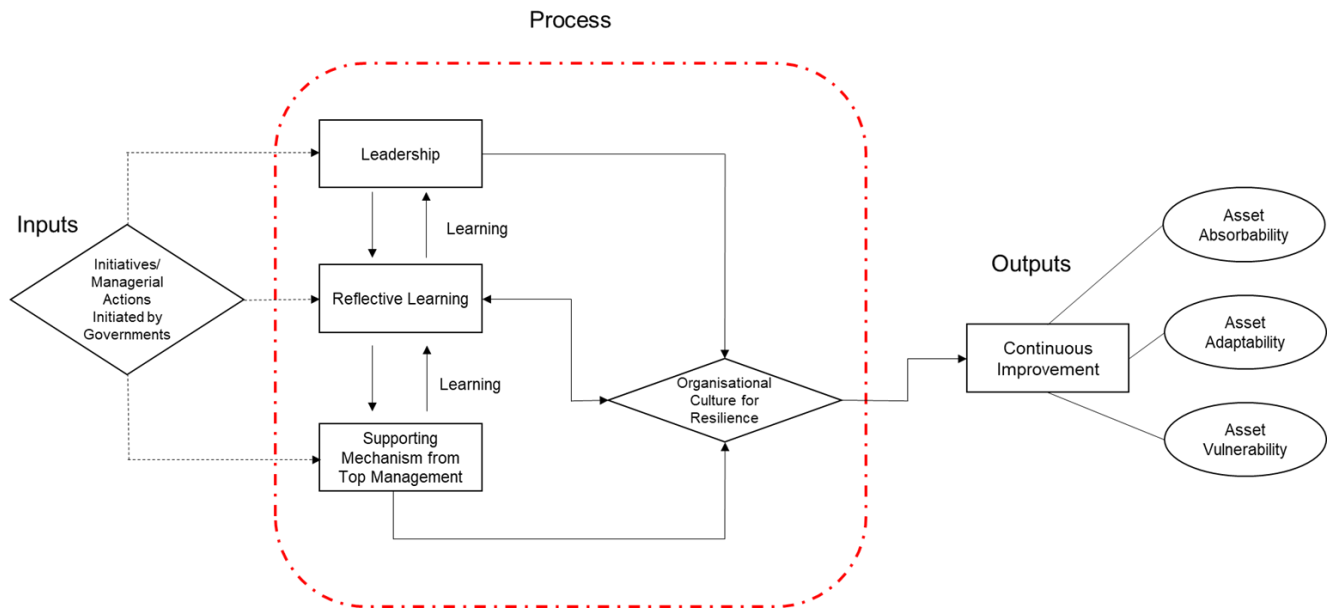

367

368 In summary, a transformational leadership training programme aims to prepare leaders for self-
369 awareness of risk and an ability to predict and execute change (Trevor and Hill, 2012).
370 Noteworthy, predictability is an element of the definition of resilience, according to the US
371 Environmental Protection Agency (2015). As also noted in Figure 4, the transport agencies
372 need to continuously learn and improve by enacting lessons learned and engaging in reflexive
373 practice to engender resilience capabilities (Love *et al.*, 2015; Liu *et al.*, 2018).

374

375 A life-cycle resilience performance measurement system (PMS) can improve transport
376 resilience from the perspective of ‘organisational learning’ as it can provide organisations with
377 an insight into: (1) the outputs of their business, specifically their adaptability and vulnerability;
378 and (2) a vision about what aspects could be improved in the future (Bourne, 1999; Neely *et*
379 *al.*, 2001). As pointed out by the UK’s Cabinet Office (2017), resilience measurement is a
380 prerequisite for building resilient infrastructure assets. However, the development of specific
381 PMSs has received limited attention (Sun *et al.*, 2020). Thus, a resilience PMS would focus on
382 measuring transport asset’s (1) adaptability to changes, (2) efficiency of a process leading to
383 adaptability, and (3) vulnerability (Liu *et al.*, 2019). With a PMS in place, governments would
384 be better positioned to understand the vulnerabilities of their assets and the actions needed to
385 ensure they are resilient.

386

387

388 Note: The arrows with dot lines indicate the possible effects of the organisation's initiatives and actions on developing their capabilities

389 Figure 6. A conceptual framework for managing government's organisational capabilities to
 390 ensure transport asset resilience

391

392 As noted in Figure 6, a change to the 'transformational leadership' from a 'transactional style',
 393 which is common in governments, can help shift the culture to be resilient and support a process
 394 of 'learning through' (i.e., how to disasters) instead of 'learning from disasters (Hofstede *et al.*,
 395 2010; Valero *et al.*, 2015; Love and Matthews, 2020). Developing an organisational culture of
 396 resilience in the public sector is a necessary part of the future-proofing process (Everley, 2011;
 397 Love *et al.*, 2017). Noteworthy, there is a reciprocal relationship between organisational culture
 398 and organisational capability. A culture of resilience, as a result of the skills development
 399 programme, will, in turn, support the development of other organisational capabilities such as
 400 the continuous improvement for an asset's adaptability, vulnerability and absorbability (Figure
 401 6) (Chang *et al.*, 2017; Cropley, 2017). To this end, culture is an integral part of shaping a
 402 resilience strategy enacted by employees (White, 2013; Hughes and Healy, 2014).

403

404

405 **6.0 Implications for Future Research**

406 Research examining the underlying dynamics of resilience abounds the literature, emphasising
407 the development of paradigms to enable positive responses to environmental changes (Figure
408 5) (Wan *et al.*, 2018). For example, the extant *known-what* research tends to focus on
409 understanding and determining the elements to include in the definition of resilience, focusing
410 on robustness, recoverability and vulnerability and identifying the barriers to developing
411 resilient infrastructure, which includes resource availability, inflexibility, and unsupportive
412 policies (Markolv *et al.*, 2018; Kermanshachi *et al.*, 2019). However, the *known-what* paradigm
413 eschews insights about improving an asset's ability to adapt and respond to external
414 disturbances.

415

416 Future research, therefore, needs to focus on identifying how to enhance the business processes
417 leading to resilient infrastructure assets (*known-how*) (Chmutina *et al.*, 2016; Liu *et al.*, 2019)
418 by engaging in a collaborative asset delivery model and utilising digital technologies (Love *et*
419 *al.*, 2021). Furthermore, within the *know-how* paradigm, an investigation into the
420 organisational capabilities that impact resilience is emerging (Blake *et al.*, 2019). Despite the
421 significant role of such capabilities in determining resilience, studies have tended to shy away
422 from identifying how to manage them (Dubey *et al.*, 2021). This has led to, for example, an
423 inability of the government in being able to develop resilient assets; thus, future studies need
424 to address the void above to enable the public sector to have robust capabilities in ensuring
425 their assets can adapt to changes (Blake *et al.*, 2019). For example, the developed managerial
426 framework places a 'strategic' (macro) emphasis on enabling continuous improvements for
427 asset's adaptability, absorbability and vulnerability *via* leadership, learning, supporting
428 mechanism and organisational culture. At a 'micro-level, the future research places emphasise

429 re-engineering governmental business processes to improve their ability to adapt and respond
430 to risks, manage uncertainties and respond to crisis events (Chmutina *et al.*, 2016).

431

432 **7.0 Conclusions**

433 Transport infrastructure is critical for supporting societies daily activities and businesses.
434 However, the infrastructure functionality is being impacted by external disturbances resulting
435 from climate-related, health, economic and social changes. Thus, transport resilience has been
436 prioritised by many governments worldwide. Yet, there is a widely accepted view that the
437 organisational capabilities of governments, particularly in the UK context for this research, are
438 critical to ensure infrastructure resilience. Still, they have received limited study within the
439 transport context. There is also an absence of research that attempts to identify how
440 government's capabilities determine resilience, leading to a knowledge void about managing
441 them to ensure resilient transport assets. This paper has sought to address this issue and thus
442 aims to generate knowledge to manage the government's capabilities for enabling transport
443 resilience.

444

445 Based on the constructed SNA network and results presented, a managerial process, which
446 incorporates five components, has been proposed to provide governments with an avenue to
447 systematically improve their organisational capabilities and the resilience of their transport
448 infrastructure assets. The components embrace (1) leadership; (2) organisational learning; (3)
449 supporting mechanism from senior management; (4) a culture adept to resilience; and (5)
450 continuous improvement (also investment) for asset's absorbability, adaptability and
451 vulnerability.

452

453 The contribution of the study presented in this paper to the literature is threefold: (1) a network
454 providing a systematic visualisation of the interactions between organisational capabilities
455 influencing asset resilience; (2) the prioritisation of governmental capabilities; and (3) the
456 development of a management framework providing a pathway that can accommodate
457 environmental changes and asset resilience. In summary, this research output provides the
458 public sector authorities with the underlying knowledge required to develop their abilities to
459 further predict risks, thinking ahead and post-crisis learning, which aid in designing and
460 implementing a robust resilience policy.
