## ABSTRACT

**Aims:** To determine COVID-19 vaccination hesitancy in healthcare professionals and healthcare students in Italy across four generations (baby boomers, generations X, Y, and Z).

**Design:** A cross-sectional descriptive study was performed through an online survey conducted from May to June 2021. The STROBE guidelines were adopted for reporting.

**Methods:** Data were collected by initially sending a survey link to a convenience sample of healthcare professionals and students, which was followed by snowball sampling. The VAX scale was validated and adopted. An ANOVA was performed to detect differences in vaccine-hesitancy beliefs between the four generational groups.

**Results:** The survey was completed by 1226 healthcare professionals and students. Worries about unforeseen future effects was the higher vaccination hesitancy factor across generations. More positive attitudes toward COVID-19 vaccination were expressed by members of generation Z than by members of generation Y and baby boomers. Members of generation X had the highest vaccination hesitancy scores in the overall scale.

**Conclusion:** The results suggest that public health campaigns should take into account the generational differences in COVID-19 vaccination hesitancy to achieve higher levels of vaccine acceptance, including among healthcare professionals and students.

**Impact:** Vaccination is the most effective strategy to tackle on the COVID-19 pandemic. The advice of health professionals strongly influences vaccination willingness in the general population. A consideration of the generational patterns in the COVID-19 vaccination hesitancy of healthcare workers and students may increase vaccination uptake in these populations, which in turn may lead to greater public acceptance of the vaccine.

## 1. INTRODUCTION

The novel coronavirus SARS-CoV-2, which causes COVID-19 disease, was first described in December 2019. By March 2020, the World Health Organization (WHO) had declared a pandemic (WHO, 2020). To combat the spread of infection, governments and healthcare systems worldwide initially adopted several non-pharmacological measures, such as social distancing, suspension or modification of working activities, restricted movement, and the obligatory use of facial masks (Roma et al., 2020) ). To conserve medical resources, patients with mild disease were managed at home and those with severe disease in the hospital. New therapeutic protocols (antiviral therapies, immune modulators, anticoagulants, monoclonal antibodies, and hyperimmune globulin) were also employed to treat disease severity or to prevent disease progression. However, none of these measures was particularly effective and the urgent need for a vaccine was quickly recognized (Mathieu et al., 2021).

Globally, as of 30 November 2021, there have been 261,435,768 confirmed cases of COVID-19, including 5,207,634 deaths. Over 4.28 billion people worldwide, corresponding to ~ 55.8% of the world population, have received at least one dose of a COVID-19 vaccine (World Health Organization [WHO], 2021), albeit with large differences among countries (Mathieu et al., 2021). The experience thus far has shown that vaccination against SARS-CoV-2 can mitigate COVID-19 severity and it is expected that it will flatten, delay, or prevent future epidemic waves of the disease.

### 1.1. Background

Although both the safety and the effectiveness of vaccination against SARS-CoV-2 are universally recognized (Center for Disease Control and Prevention [CDC], 2021) and countries worldwide are striving to achieve COVID-19 immunity within their populations, vaccination hesitancy remains a major obstacle both in the general population (Bhagianadh & Arora, 2021) and among healthcare workers and students (Holzmann-Littig et al., 2021). The reasons include concerns about vaccine

1  
2  
3 safety, a lack of trust in the government or in the healthcare system, and a suspicion of profiteering  
4 by pharmaceutical companies (Normura et al., 2021). These attitudes have been supported by the  
5 rapid dissemination of fake news regarding the risks of vaccination. Fake news is defined as  
6 “fabricated information that imitates news media content in form but not in organizational process  
7 or intent, which overlaps with other information disorders, such as misinformation - false or  
8 misleading information - and disinformation, which is false information that is deliberately  
9 disseminated to deceive people” (Lazer et al., 2018). The problem is compounded by the fact that  
10 fake news spreads faster and is more highly entrenched than real news, facilitated by the rapid  
11 propagation of information, regardless of its source or quality, by social media. The WHO (2020)  
12 has defined this overabundance of information as an “infodemic” that is spreading fear,  
13 uncertainty, and anxiety with respect to health-related behaviors. During the pandemic, it has  
14 resulted in a fragmented response that has hampered pandemic containment strategies. Public  
15 health measures adopted to stop the spread of the virus have been paralleled by the spread of  
16 various conspiracy theories (European Commission, 2020) that have not only encouraged a general  
17 distrust of healthcare systems but have also led to a robust anti-vaccine movement and in some  
18 instances to violent demonstrations, all of which have hampered efforts to achieve global  
19 immunization (Herrera-Peco et al., 2021).

34  
35  
36  
37  
38  
39  
40  
41  
42 Vaccine hesitancy on the part of healthcare workers (HCWs) has far-reaching impact. For ethical  
43 and scientific reasons this group should be promoters of vaccination (Squeri et al., 2017), given  
44 their interest in protecting both their patients and the global community. However, vaccination  
45 among HCWs has always been a controversial issue: for example, the coverage rate in HCWs for  
46 seasonal influenza vaccination in European countries from 2015 to 2018 was < 40% and in Italy it  
47 was < 20% (ECDC, 2018).

1  
2  
3 In the US, only one-third of HCWs were willing to be vaccinated with the COVID-19 vaccine as  
4 soon as it became available, prior to its Emergency Use Authorization (EUA), with a majority  
5 choosing to wait several months before deciding (Shekhar et al., 2021). Another study suggested  
6 that being a nondoctor healthcare personnel (i.e., nurse/midwife) was an independent risk factor  
7 for refusing or postponing COVID-19 vaccination, with the most common reasons for these  
8 decisions being doubt about the efficacy of the vaccine, distrust of its content, and a fear of side  
9 effects (Esen et al., 2021). Vaccine hesitancy in HCWs is an important issue due to its potential  
10 consequences for the HCWs themselves and because higher patient mortality rates were reported  
11 in hospitals with a lower percentage of vaccinated employees. In response, countries such as the  
12 US, Canada, Australia, and the UK have implemented policies whereby certain vaccinations are a  
13 legal requirement for HCWs. In Italy, a law was passed in April, 2021 requiring that all HCWs be  
14 vaccinated against COVID-19 or face unpaid suspension from work. The law is in effect until  
15 December 31, 2021, and it also includes healthcare students participating in clinical placements.  
16  
17 In the case of COVID-19 vaccination, physicians and nurses in some countries have been  
18 suspended from hospital practice. These actions have been supported by the European Court of  
19 Human Rights in Strasbourg, which ruled that obligatory vaccination does not contravene the  
20 European Convention on Human Rights (Wazyńska-Finck, 2021).  
21  
22

23  
24 In this study, we examined whether vaccine hesitancy among healthcare professionals and students  
25 is related to generational differences. Our study draws on recent work by Nomura et al. (2021),  
26 who showed that a public health campaign specifically targeting individuals with vaccine  
27 hesitancy may help to increase COVID-19 vaccine uptake. We hypothesized that a generation-  
28 specific approach, by building upon the cultural experiences, attitudes, values, and beliefs shared  
29 by a particular age group (Şenyuva, 2018), would be effective in addressing COVID-19 vaccine

hesitancy among HCWs and healthcare students and thus in promoting vaccine uptake by this population.

The recent healthcare literature recognizes four generations that differ in their professional and work-related attitudes, values, and beliefs: (1) the baby boomers (BB) generation values organizational loyalty and a strong work ethic; (2) generation X prioritizes a work-life balance; (3) generation Y is innovation-oriented and values change over stability; (4) generation Z is the first fully native digital generation and it has intensively integrated social media into everyday life (Schmitt et al., 2019). Our hypothesis is based on the assumption that these generational differences affect vaccination hesitancy, such that generational differences in professional and work-related attitudes, values, and beliefs should be considered in vaccination campaigns the healthcare professionals and students are exposed in taking care of vulnerable people and vaccination is supposed to contribute to patient safety at the individual and at the organizational level. Furthermore, the impact of the current COVID-19-related “infodemic” may differ in different generations. Thus, in this study, healthcare professionals and students in Italy distributed across four generations were assessed for their attitudes towards COVID-19 vaccination.

## **2. THE STUDY**

### **2.1. Aims**

The aim of this study was to reveal possible generational differences in attitudes towards COVID-19 vaccination in HCWs and healthcare students in Italy.

### **2.2. Design**

A cross-sectional, descriptive study was performed from May to June 2021, through an online survey of HCWs and healthcare students in Italy. The study period coincided with the third wave

1  
2  
3 of the COVID-19 pandemic. The STrengthening the Reporting of Observational studies in  
4 Epidemiology (STROBE) guidelines were adopted for reporting.  
5  
6

### 7 8 **2.3. Participants**

9  
10 Healthcare professionals and students were recruited in a convenience sampling approach, via  
11 formal and informal networks throughout Italy. The online survey was initially disseminated  
12 within healthcare professionals' and students' associations and social networks groups at the  
13 national level. Snowball sampling contributed to further dissemination of the survey among the  
14 target population. Participants were categorized into generations according to the following  
15 criteria, drawn from the literature: BB participants were born between 1946 and 1964; generation  
16 X participants between 1965 and 1980, generation Y participants between 1981 and 1996, and  
17 generation Z participants after 1997 (Schmitt et al., 2019).  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27

### 28 **2.4. Data collection**

29  
30 Data were collected in an online survey approach implemented in LimeSurvey. To prevent  
31 inappropriate accesses, a CAPTCHA system was adopted to prevent inappropriate accesses: in  
32 detail participants were asked to report the sum score of a basic operation, thus confirming that the  
33 participant was human and not an internet-bot. A cookies recording system was also adopted to  
34 prevent duplicated or multiple imputations from the same user's device.  
35  
36  
37  
38  
39  
40  
41

### 42 **2.5. Ethical considerations**

43  
44 Data collection and analysis were designed to ensure data confidentiality and were conducted in  
45 accordance with national and European laws (GDPR, 2018) and the Personal Data Act (523/1999).  
46  
47 The electronic data were saved in a protected folder, accessible only by the principal investigator.  
48  
49 The survey platform was protected by a strong-recognized password and a two-step authentication  
50 method. On the first screen of the survey, participants were shown a statement that included details  
51 of the study and data handling. Survey submission was interpreted as the participant's consent.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Due to the type of data collected and the online data collection approach, neither ethical approval  
4 nor administrative permissions were necessary.  
5  
6

7  
8 The online survey was designed according to the Code of Ethics of the American Association for  
9 Public Opinion Research (AAPOR, 2021). The participation was voluntary to all participants and  
10 in compliance with the standards of informed consent, data confidentiality and anonymity (EU  
11 2016/679). Due to the type of data collected, the data collection approach and the descriptive  
12 design of the study, neither administrative nor ethical approvals were necessary (Decreto del  
13 Ministero della Salute, 2013).  
14  
15  
16  
17  
18  
19

## 20 **2.6. Measures**

### 21 *2.6.1. Instrument description*

22  
23  
24 The VAX scale consists of 12 items rated on a Likert scale of agreement, ranging from one  
25 (strongly disagree) to seven (strongly agree) (Martin & Petrie, 2017). In this study, it was used  
26 with respect to COVID-19 vaccination. The 4-factors model was based on previous psychometric  
27 testing and included: mistrust of vaccine benefit (3 items); worries about unforeseen future effects  
28 (3 items); concerns about commercial profiteering (3 items); and preference for natural immunity  
29 (3 items) (Martin & Petrie, 2017). Lower scores were considered to reflect a more positive attitude  
30 toward the vaccine. The “mistrust of vaccine benefit” factor was defined as the reversed score of  
31 the following items: “I feel safe after being vaccinated”, “I can rely on vaccines to stop serious  
32 infectious diseases”, and “I feel protected after getting vaccinated.”  
33  
34  
35  
36  
37  
38  
39

40 Socio-demographic, work-related (i.e., work or placement in a COVID area), and health-related  
41 (COVID infection exposure) data were collected to further describe the sample (see supplementary  
42 file S1).  
43  
44  
45  
46

## 47 **2.7. Data analysis**

1  
2  
3 The data were analyzed using Stata v12 (StataCorp., 2011). Multivariate outliers were checked by  
4 adopting the “bacon” package in Stata v12. Descriptive statistics were calculated to describe the  
5 sample. VAX scale scores were calculated as the mean and standard deviation (SD) for the total  
6 scale and for each factor. Statistical differences were detected by performing an ANOVA for the  
7 VAX scale and its factors by generation. Statistical significance was defined as a p-value <0.05.  
8  
9 The survey was designed such that answers were mandatory for all items of the VAX scale, while,  
10 the socio-demographic were not mandatory; missing data management was not necessary.  
11  
12  
13  
14  
15  
16  
17  
18

### 19 *2.7.1. Sample size*

20  
21 For a confirmatory factor analysis (CFA), a participant to parameter ratio ranging from 10:1 to  
22 20:1 is recommended (Kline, 2015;). Accordingly, the required sample size was between 120 and  
23 240 participants. Thus, to detect a statistically significant difference among the four generational  
24 groups based on an ANOVA and by considering an alpha error of 0.05 and a power of 0.99, the  
25 minimum sample size for our study was 384 participants.  
26  
27  
28  
29  
30  
31  
32

## 33 **2.8. Validity, reliability, and rigor**

### 34 *2.8.1. Content validity*

35  
36 A panel of four researchers fluent in Italian and English performed a forward and backward  
37 translation to ensure content validity. The panel achieved agreement on the Italian translation of  
38 the scale; neither the deletion of an item nor the cultural adaptation of an item was needed. The  
39 Italian version was blindly back-translated into English by a native English speaker. Finally, the  
40 original English version and the English back-translated version were blindly compared by another  
41 researcher, fluent in English and familiar with the topic. The third independent researcher stated  
42 the content equivalence of the two versions and therefore the content validity of the Italian  
43 translation as well.  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54

### 55 *2.8.2. Validity and reliability*

1  
2  
3 Cronbach's alpha was adopted to test instrument reliability. Values  $>0.90$  are considered excellent,  
4 values  $>0.70$  and  $\leq 0.90$  good, values  $>0.60$  and  $\leq 0.70$  acceptable, and values  $\leq 0.60$  non-acceptable  
5  
6 (DeVellis, 2016). A CFA was performed to test the VAX scale's construct validity. Fit indices  
7  
8 were calculated to confirm the model's validity. Those indices are considered acceptable for a  
9  
10 RMSEA (root mean square error of approximation) and SRMR (standardized root mean residual)  
11  
12  $<0.08$ , and based on a CFI (comparative fit index) and TLI (Tucker-Lewis Index)  $>0.90$  (Kline,  
13  
14  
15 2015).  
16  
17  
18  
19  
20

### 21 **3. RESULTS**

22  
23 The survey questionnaire was completed by 1226 healthcare students and healthcare professionals.  
24  
25 The majority were female (75.5%; 926/1226) and the mean age was 30.1 years (SD=12.42;  
26  
27 median=24; min=20; max=70). Healthcare students comprised 58.0% of the sample (711/1226)  
28  
29 and healthcare professionals the remainder. Among the former, most were nursing students  
30  
31 (84.4%; 600/711); 15.6% included students in medicine, dentistry, psychology, pharmacy, or  
32  
33 technical areas (e.g., lab or X-ray technicians). Healthcare professionals made up 42.0%  
34  
35 (515/1226) of the study population; the majority were nurses (430/515; 83.5%) and the others  
36  
37 either physicians or technicians (e.g., lab or X-ray technicians).  
38  
39

40  
41 According to the generational distribution, 4.9% (60/1226) were BB, 17.4% belonged to  
42  
43 generation X (213/1226), 27.1% (332/1226) to generation Y, and 50.6% (621/1266) to generation  
44  
45 Z. A clinical placement in a COVID-19 clinical setting in the last 12 months was reported by 6.0%  
46  
47 (43/711) of the healthcare students; 45.6% (235/515) of the healthcare professionals had worked  
48  
49 in a COVID-19 area in the last 12 months. Overall, 13.6% (167/1226) of the total sample reported  
50  
51 infection with COVID-19 and 83.8% (1027/1226) never having been infected. Data were missing  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 for 2.6% (32/1226). Most of the participants (64.4%; 790/1226) also reported living with or caring  
4 for a frail person in their close family network (Table 1).  
5

6  
7 No multivariate outliers were detected in the data distribution. The CFA and fit indexes confirmed  
8 the previously determined 4-factors model: RMSEA=0.068 (90% confidence interval [CI]=0.061–  
9 0.075), SRMR=0.045, TLI=0.947, CFI=0.962. Cronbach's alpha was 0.88 in the overall scale and  
10 ranged from 0.75 to 0.84 among factors. Both the validity and the reliability of the scale were  
11 confirmed.  
12  
13

14  
15 Based on the descriptive statistics, the overall mean value for the VAX scale was 2.78 (SD=0.93,  
16 median=2.67; min=1; max=7). For 25% of the sample the score was below 2.17 (Q1) and for 25%  
17 it was over 3.25 (Q3). The overall mean score of the factor “mistrust of vaccine benefit” was 1.92  
18 (SD=0.97; median=1.67; min=1; max=7). For 25% of the sample the score was below 1.33 (Q1)  
19 and for 25% it was over 2.00 (Q3). The mean score of the factor “worries about unforeseen future  
20 effects” was 4.31 (SD=1.29, median=4.33; min=1; max=7). For 25% of the sample the score was  
21 below 2.67 (Q1) and for 25% it was over 5.33 (Q3). The mean score of “concerns about  
22 commercial profiteering” was 2.14 (SD=1.26; median=1.67; min=1; max=7). For 25% of the  
23 sample the score was below 1.00 (Q1) and for 25% it was over 2.67 (Q3). The mean score of the  
24 “preference for natural immunity” factor was 2.73 (SD=1.30; median=2.67; min=1; max=7). For  
25 25% of the sample the score was below 1.67 (Q1) and for 25% it was over 3.67 (Q3).

39  
40  
41  
42  
43

44 Among the four studied generations, generation Z had the lowest score in the overall VAX scale  
45 and thus a highly positive attitude toward COVID-19 vaccination (mean=2.62; SD=0.79;  
46 median=2.50; min=1; max=7; Q1=2.08; Q3=3.00). The highest score and thus the most negative  
47 attitude toward vaccination was that of generation X (mean=3.00; SD=1.04; median=2.83; min=1;

59  
60

max=7; Q1=2.33; Q3=3.58). The difference between these generations was statistically significant (F=13.32,  $p<0.001$ ).

The same pattern was detected when the generations were compared for each factor; the differences in the mean scores were statistically significant. The factor “worries about unforeseen future effects” consistently had the highest score, ranging between a mean of 4.15 (SD=1.20; median=4.33; min=1; max=7; Q1=3.33; Q3=5.00) in the generation Z group and a mean of 4.59 (SD=1.32; median=4.67; min=1; max=7; Q1=4.00; Q3=5.33) in the generation X group. The scores for the factor “preference for natural immunity” were similar for BB, generation X, and generation Y: 2.92 (SD=1.28; median=2.83; min=1; max=7; Q1=2.00; Q3=3.67), 2.89 (SD=1.37; median=2.67; min=1; max=7; Q1=2.00; Q3=4.00), and 2.87 (SD=1.41; median=2.67; min=1; max=7; Q1=2.00; Q3=3.83), respectively. Overall, the differences in the scores of generation X were higher and those of generation Z lower than the scores of BB and generation Y. The mean scores and inferential statistics are reported in Table 2.

### 3.1. Sensitivity analysis

Given the differences in the generational distribution of healthcare students vs. healthcare professionals, the data of the two groups were analyzed separately.

Among healthcare professionals, generation Z participants had a more positive (mean=2.48; SD=0.67) and generation Y a more negative attitude (mean=2.98; SD=1.06) toward vaccination, while among healthcare students the highest score, indicating the most negative attitude, was that of the two BB members (mean=3.41; SD=0.35). The mean of the VAX scale total score differed significantly for both healthcare professionals ( $p=0.008$ ) and healthcare students ( $p=0.007$ ). Statistically significant generational differences were also detected among healthcare students for the factors “mistrust of vaccine benefit” ( $p<0.001$ ) and “worries about unforeseen future effects”

1  
2  
3 (p=0.036), and among healthcare professionals for the factors “mistrust of vaccine benefit”  
4  
5 (p=0.022) and “concerns about commercial profiteering” (p=0.015). The mean scores and results  
6  
7 of the statistical analyses for the two groups are reported in Tables 3 and 4.  
8  
9

#### 10 11 12 **4. DISCUSSION** 13

14 This is the first study to explore generational differences in the hesitancy of healthcare  
15 professionals and students in Italy regarding vaccination against COVID-19. Overall, our findings  
16 revealed a high vaccine hesitancy across all four studied generations, largely due to concerns about  
17 unforeseen future effects. Previous studies found that vaccine safety issues were the most  
18 important determinant of COVID-19 vaccine hesitancy in HCWs (Li et al., 2021;), college students  
19 (Salerno et al., 2021), and the general population (Reiter et al., 2020). Possible explanations for  
20 the concerns of HCWs are: (1) misinformation transmitted on social media, (2) limited resources,  
21 increased workload, and (3) inadequate information on the risks or benefits of the vaccine  
22 (Paterson et al., 2016).  
23  
24

26  
27  
28  
29  
30  
31  
32  
33  
34

35 Our identification of these concerns and their sources suggests strategies for addressing vaccine  
36 hesitancy in healthcare professionals and students, including a greater focus on the long-term  
37 safety of the vaccine that draws on scientific evidence. Building confidence in vaccines, and in  
38 their efficacy and safety in particular, may in turn contribute to both groups recommending the  
39 vaccine to others. A previous study showed that the advice of HCWs is highly trusted by their  
40 patients, including with respect to vaccination, especially if they themselves have been vaccinated  
41 or intend to be vaccinated (Paterson et al., 2016). HCWs were shown to act as role models for the  
42 population and to have a positive influence on patients' vaccination attitudes (Burden et al., 2021).

58  
59  
60

Vaccinated HCWs are more likely to recommend vaccination to patients and, in general, to others,

1  
2  
3 whereas doubtful or hesitant HCWs may be reluctant to recommend vaccination to either their  
4 patients or members of their community.  
5  
6

7  
8 In the development of efforts to increase the acceptability of the COVID-19 vaccine, several  
9 factors must be taken into account, including contextual influences, vaccine-specific issues,  
10 individual/social group influences, and personal values, as all of these will guide individual  
11 decision-making (Şenyuva, 2018). Health beliefs related to vaccination are influenced by  
12 perceptions of the risk and severity of the respective disease as well as the efficacy, safety, and  
13 potential side effects of the vaccine. Previous studies suggested an association with the  
14 acceptability of vaccines such as the seasonal influenza vaccine (Ling et al., 2019) and the human  
15 papillomavirus vaccine (Reiter et al., 2009). However, personal beliefs are dynamic and modifying  
16 them can affect behavior, which should be borne in mind in future educational interventions and  
17 vaccination campaigns against COVID-19. This approach has been successfully used to improve  
18 knowledge, attitudes, and uptake of other vaccines (McRee et al., 2018).

33 That vaccine acceptance vs. hesitancy is closely related to the level of knowledge about the vaccine  
34 and the source of information was demonstrated by Gallè et al. (2021) in a study of Italian  
35 undergraduate students. Therefore, an analysis of vaccine acceptance among different groups  
36 within a population may result in more effective and more informative campaigns to counteract  
37 disinformation.  
38  
39  
40  
41  
42  
43

44 Among HCWs, several interventions were shown to be effective in increasing both the rate of  
45 influenza vaccination and trust in the healthcare system. These included educational talks/videos,  
46 an extensive educational campaign, informed consent, audit and telephone interviews with  
47 unvaccinated HCWs, a medical interview with a hospital executive regarding noncompliance, and  
48 visible leader support (Paterson et al., 2016). However, given the many possible forms of active

7  
8  
9

#### 10 **4.1. Comparison between generations**

11  
12 Our study identified a more positive attitude toward COVID-19 vaccination in generation Z than  
13 in the other generations. Generation Z was also the youngest generation in our study and its  
14 willingness to be vaccinated may be related to a desire for an active social life, freedom of daily  
15 movement, and travel. In addition, as a digitally savvy generation, generation Z may be less  
16 susceptible to fake news and thus better able to recognize reliable information about vaccination.  
17  
18

19 As future healthcare providers, healthcare students generally have a high level of e-Health literacy  
20 and are therefore skilled in locating, using, and critically appraising health information online,  
21 which in turn would improve their competency in decision-making. However, while students may  
22 be confident in obtaining information on the internet, they often lack the knowledge needed to  
23 make decisions about their own health options. This point deserves attention as previous studies  
24 have pointed out that vaccine acceptance and knowledge are closely related, thus emphasizing the  
25 key role of correct information in countering vaccination hesitancy (Gallè et al., 2021).  
26

31  
32  
33  
34  
35  
36  
37  
38  
39

40 A positive attitudes toward COVID-19 vaccination was also identified in generation Y, consistent  
41 with the openness of this generation to innovation and change, especially as “the first generation  
42 of digital natives” (Palfrey & Gasser, 2008). Generation Y is characterized by a high level of  
43 confidence in using e-Health information, a recognition of reliable online resources, experience in  
44 working in healthcare settings, and a high degree of professionalism, all of which lead to balanced  
45 health-related decision-making.

56  
57  
58  
59  
60

1  
2  
3 The attitude of BB to COVID-19 vaccination was better than that of generation X or Y, in line  
4 with the work ethic, orientation towards the common good, and the strong sense of social  
5 responsibility that distinguishes this older generation (Şenyuva, 2018). The general lack of digital  
6 competency of BB is compensated by a high level of institutional commitment, including with  
7 respect to vaccination. In previous studies, increasing age was identified as an independent  
8 predictor of vaccination acceptance ), perhaps because older age is also associated with a high risk  
9 of comorbidities, resulting in a higher risk tolerance by BB than by HCWs in younger age groups.  
10  
11 Vaccination willingness in generation X was between that of BB and generation Y. Members of  
12 generation X, while digitally competent, lack institutional commitment, are more oriented to  
13 independent work, and have a general resistance to authority (Schmitt et al., 2019). These  
14 characteristics are consistent with our finding of a higher vaccine hesitancy in this group.  
15  
16 The generational differences detected in our study demonstrate the need for communication  
17 channels tailored to reach people of different generations and thus ensure the effective delivery of  
18 information. For example, while informal discussions through face-to-face or written  
19 communication are likely to be effective in BB, members of generations X, Y, and Z may be best  
20 reached through technology. However, differences between the latter generations should also be  
21 considered. For generations Y and Z, immediate feedback is important, given that their members  
22 mainly communicate through instant messaging, whereas generation X is likely to be more  
23 receptive to a dialectic form of communication, such as a more direct involvement in the public  
24 debate.  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48

49 A vaccination campaign that takes into account the generational differences among healthcare  
50 professionals and students, especially their choice of communication channels, may result in  
51 improved communication and more effective content. Particular attention should be paid to the  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 methods used to reach members of generation X, as the high level of skepticism and individualism  
4 of this group (Kupperschmidt, 2000) may translate into a higher level of vaccine hesitancy.  
5  
6 Accordingly, communication with generation X should be aimed at reducing concerns about  
7  
8 unforeseen future effects of vaccination (Reiter et al., 2020). By contrast, for generation Z, a cohort  
9  
10 likely to be more open to vaccination, the focus should be on behavioral recommendations and  
11  
12 vaccine efficacy (Reiter et al., 2020). The preference for natural immunity was similar among BB  
13  
14 and members of generations X and Y, indicating that for this issue the same message can be  
15  
16 developed but its delivery will require different marketing strategies.  
17  
18

19  
20  
21 The consequences of the generational differences underlying vaccine hesitancy were demonstrated  
22  
23 in a comparison of healthcare professionals vs. healthcare students. Vaccine hesitancy in  
24  
25 healthcare professionals was related to a “mistrust of vaccine benefit” and to “concerns about  
26  
27 commercial profiteering,” whereas in healthcare students it was related to “mistrust of vaccine  
28  
29 benefit” and to “worries about unforeseen future effects.” This difference highlights the  
30  
31 importance of targeting vaccination campaigns aimed at specific populations.  
32  
33

34  
35 Profiling HCWs and healthcare students’ vaccination hesitancy according to the generational  
36  
37 category contributes to tailoring the COVID-19 vaccination campaign and to potentially increase  
38  
39 vaccination uptake among the reluctant clusters. Consequently, by implementing a new  
40  
41 vaccination approach based on attitudes, values, and beliefs in different age groups, the decision-  
42  
43 and policy- makers can tackle vaccination uptake and public health strategies in a tailored way, so  
44  
45 to overcome vaccination hesitancy. Moreover, our findings provide useful insights to further  
46  
47 designing intervention studies to implement tailored educational strategies in the vaccination  
48  
49 campaigns.  
50  
51

#### 52 53 54 **4.2. Strengths and limitations of the study** 55 56 57 58 59 60

1  
2  
3 While generational differences in work environments have been examined in many studies, to our  
4 knowledge this is the first study to examine intergenerational differences in healthcare  
5 professionals and students with respect to COVID-19 vaccination. A particular strength of this  
6 study was the large sample, obtained by employing a mixed approach to sampling and survey  
7 dissemination.  
8  
9

10  
11  
12 Nonetheless, the limitations of the study must also be noted. First of all, because the survey was  
13 online-based, those population groups less likely to engage in online communication and/or to  
14 have less access to the internet may have been under-represented. Furthermore, self-selection bias  
15 must be considered, as healthcare professionals and students with a greater propensity to be  
16 vaccinated might have been more likely to participate. Also, due to the cross-sectional design of  
17 the study, differences among groups, but not their causal relationships, were identified. Finally,  
18 our quantitative approach may have missed some aspects of the attitudes, values, and beliefs  
19 regarding vaccination against COVID-19: these might be better understood in a qualitative  
20 approach.  
21

## 38 **5. CONCLUSION**

39 Addressing the generational differences in attitudes, values, and beliefs that lead to vaccine  
40 hesitancy in HCWs and healthcare students may contribute to generationally tailored COVID-19  
41 vaccination campaigns and thus potentially to increased vaccination uptake among reluctant  
42 groups. Vaccine hesitancy within the healthcare community may best be overcome through  
43 vaccination campaigns that directly address the long-term safety of the vaccine, based on scientific  
44 evidence. However, the vaccination-related concerns of BB and members of generations Y and Z  
45 were shown to differ from those of generation X. Recognition of these differences in the

**Table 1.** Sample description.

	<b>Healthcare students (N=711)</b>	<b>Healthcare professionals (N=515)</b>	<b>Total (N=1266)</b>
Baby boomers	2 (0.28%)	58 (11.26%)	60 (4.74%)
Generation X	16 (2.25%)	197 (38.25%)	213 (16.82%)
Generation Y	126 (17.72%)	206 (40.00%)	332 (26.22%)
Generation Z	567 (79.74%)	54 (10.49%)	621 (49.05%)
Nursing	600 (84.39%)	430 (83.50%)	1030 (81.36%)
Other disciplines	111 (15.61%)	85 (16.50%)	196 (15.48%)
Exposed to COVID-19 in a clinical setting	43 (6.05%)	235 (45.63%)	278 (21.96%)
SARS-CoV-2 infection†	77 (11.16%)	90 (17.86%)	167 (13.62%)
Next of kin - frail person	471 (66.24%)	319 (61.94%)	790 (62.40%)

†32 missing values (21 healthcare students and 11 healthcare professionals).

**Table 2.** Generational differences in vaccine-hesitant beliefs (ANOVA).

	Generation					p-value
	Baby boomers	X	Y	Z	F	
	(N=60) mean (SD)	(N=213) mean (SD)	(N=332) mean (SD)	(N=621) mean (SD)		
<b>MISTRUST OF VACCINE BENEFIT</b>	1.82 (0.87)	2.10 (1.16)	2.07 (1.12)	1.79 (0.80)	9.39	<.001
<b>WORRIES ABOUT UNFORESEEN FUTURE EFFECTS</b>	4.48 (1.47)	4.59 (1.32)	4.43 (1.37)	4.15 (1.20)	7.88	<.001
<b>CONCERNS ABOUT COMMERCIAL PROFITEERING</b>	2.35 (1.18)	2.41 (1.40)	2.28 (1.42)	1.95 (1.10)	9.98	<.001
<b>PREFERENCE FOR NATURAL IMMUNITY</b>	2.92 (1.28)	2.89 (1.37)	2.87 (1.41)	2.58 (1.21)	5.57	<.001
<b>VAX scale score</b>	2.89 (0.94)	3.00 (1.04)	2.91 (1.03)	2.62 (0.79)	13.32	<.001

**Table 3.** Generational differences in vaccine-hesitant beliefs among healthcare students (ANOVA).

	Generation					p-value
	Baby boomers	X	Y	Z	F	
	(N=2) mean (SD)	(N=16) mean ( $\pm$ SD)	(N=126) mean (SD)	(N=567) mean (SD)		
<b>MISTRUST OF VACCINE BENEFIT</b>	2.00 (0.00)	2.73 (1.65)	1.97 (1.10)	1.80 (0.80)	6.76	<b>&lt;.001</b>
<b>WORRIES ABOUT UNFORESEEN FUTURE EFFECTS</b>	5.33 (0.47)	4.81 (1.26)	4.37 (1.28)	4.16 (1.21)	2.85	<b>0.036</b>
<b>CONCERNS ABOUT COMMERCIAL PROFITEERING</b>	3.00 (0.94)	2.64 (1.49)	2.08 (1.26)	1.97 (1.10)	2.54	0.056
<b>PREFERENCE FOR NATURAL IMMUNITY</b>	3.33 (0.94)	2.71 (1.26)	2.71 (1.41)	2.59 (1.21)	0.60	0.614
<b>VAX scale</b>	3.41 (0.35)	3.22 (1.06)	2.78 (0.97)	2.63 (0.80)	4.10	<b>0.007</b>

**Table 4.** Generational differences in vaccine-hesitant beliefs among healthcare professionals (ANOVA).

	Generation					p-value
	Baby boomers	X	Y	Z	F	
	(N=58) mean (SD)	(N=197) mean (SD)	(N=206) mean (SD)	(N=54) mean (SD)		
<b>MISTRUST OF VACCINE BENEFIT</b>	1.81 (0.88)	2.04 (1.10)	2.13 (1.12)	1.70 (0.70)	3.23	<b>.022</b>
<b>WORRIES ABOUT UNFORESEEN FUTURE EFFECTS</b>	4.45 (1.48)	4.57 (1.33)	4.47 (1.42)	4.03 (1.07)	2.25	.082
<b>CONCERNS ABOUT COMMERCIAL PROFITEERING</b>	2.33 (1.19)	2.39 (1.39)	2.40 (1.50)	1.75 (0.99)	3.52	<b>.015</b>
<b>PREFERENCE FOR NATURAL IMMUNITY</b>	2.91 (1.30)	2.91 (1.38)	2.97 (1.40)	2.45 (1.18)	2.10	.099
<b>VAX scale score</b>	2.87 (0.95)	2.98 (1.04)	2.99 (1.06)	2.48 (0.67)	4.00	<b>.008</b>

2  
3 **Supplementary file 1 (S1) - List of survey items and response options.**  
4

5 ***Vax scale items:***  
6

- 7  
8 1. I feel safe after being vaccinated  
9  
10 2. I can rely on vaccines to stop serious infectious diseases.  
11  
12 3. I feel protected after getting vaccinated.  
13  
14 4. Although most vaccines appear to be safe, there may be problems that we have not yet discovered.  
15  
16 5. Vaccines can cause unforeseen problems in children.  
17  
18 6. I worry about the unknown effects of vaccines in the future.  
19  
20 7. Vaccines make a lot of money for pharmaceutical companies, but do not do much for regular  
21  
22 people.  
23  
24 8. Authorities promote vaccination for financial gain, not for people's health.  
25  
26 9. Vaccination programs are a big con.  
27  
28 10. Natural immunity lasts longer than a vaccination.  
29  
30 11. Natural exposure to viruses and germs gives the safest protection.  
31  
32 12. Being exposed to diseases naturally is safer for the immune system than being exposed through  
33  
34 vaccination.  
35  
36  
37  
38  
39

40 ***Liket scale:***

41 *1=Strongly disagree; 2=disagree; 3=slightly disagree; 4=Neither agree nor disagree; 5=slightly*

3 ***Sociodemographic (response options):***  
4

5 - Gender (Male/Female).  
6

7 - Age (Years).  
8

9  
10 - Student or healthcare professional [student, fill in the response options (nursing, medicine, dentistry,  
11 psychology, pharmacy or technical area); healthcare professionals: fill in the response options  
12 (nursing, medicine, dentistry, psychology, pharmacy or technical area)].  
13  
14

15  
16  
17 - For students - Have you attended a clinical placement in a COVID-19 clinical setting in the last 12  
18 months? (Yes/No).  
19

20  
21 - For healthcare professionals – Have you worked in a COVID-19 clinical setting in the last 12  
22 months? (Yes/No).  
23

24  
25  
26 - Have you been infected by COVID-19? (Yes/No).  
27

28  
29 - Do you live with or caring for frail person in your close family network? (Yes/No).

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No.
<b>Title and abstract</b>	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	1
<b>Introduction</b>			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	2-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
<b>Methods</b>			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5,6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	5,6
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	-
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	7-9
Bias	9	Describe any efforts to address potential sources of bias	7
Study size	10	Explain how the study size was arrived at	8
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	7-9
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	8-9
		(b) Describe any methods used to examine subgroups and interactions	7-9
		(c) Explain how missing data were addressed	6,9
		(d) If applicable, describe analytical methods taking account of sampling strategy	7-9
		(e) Describe any sensitivity analyses	7-9, 11
<b>Results</b>			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	6,7
		(b) Give reasons for non-participation at each stage	-
		(c) Consider use of a flow diagram	-
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	4,5
		(b) Indicate number of participants with missing data for each variable of interest	n.a.
Outcome data	15*	Report numbers of outcome events or summary measures	7-9
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear	9-11

		which confounders were adjusted for and why they were included	
		(b) Report category boundaries when continuous variables were categorized	9-11
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	-
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	10-11
<b>Discussion</b>			
Key results	18	Summarise key results with reference to study objectives	11-16
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	15,16
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	11-16
Generalisability	21	Discuss the generalisability (external validity) of the study results	11-16
<b>Other information</b>			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	✓

\*Give information separately for exposed and unexposed groups.

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at [www.strobe-statement.org](http://www.strobe-statement.org).
